## Lecture 21: Dynamic Programming III

## Lecture Overview

- Subproblems for strings
- Parenthesization
- Edit distance (\& longest common subseq.)
- Knapsack
- Pseudopolynomial Time

## Review:

* 5 easy steps to dynamic programming
(a) define subproblems
count \# subproblems
(b) guess (part of solution)
count \# choices
(c) relate subproblem solutions
compute time/subproblem
(d) recurse + memoize time $=$ time/subproblem $\cdot \#$ sub-
problems
OR build DP table bottom-up
check subproblems acyclic/topological order
(e) solve original problem: = a subproblem

OR by combining subproblem solutions $\quad \Longrightarrow$ extra time

* problems from L20 (text justification, Blackjack) are on sequences (words, cards)
* useful problems for strings/sequences $x$ :
suffixes $x[i:]$
prefixes $x[: i]$
$\Theta(|x|) \quad \leftarrow$ cheaper $\Longrightarrow$ use if possible
substrings $x[i: j]$
$\} \Theta\left(x^{2}\right)$

## Parenthesization:

Optimal evaluation of associative expression $A[0] \cdot A[1] \cdots A[n-1]-$ e.g., multiplying rectangular matrices

Figure 1:
2. guessing $=$ outermost multiplication $(\underbrace{\cdots}_{\uparrow_{k-1}})(\underbrace{\cdots}_{\uparrow_{k}})$

$$
\Longrightarrow \# \text { choices }=O(n)
$$

1. subproblems $=$ prefixes suffixes? NO
$=$ cost of substring $A[i: j]$
$\Longrightarrow$ \# subproblems $=\Theta\left(n^{2}\right)$
2. recurrence:

- $\mathrm{DP}[i, j]=\min (\mathrm{DP}[i, k]+\mathrm{DP}[k, j]+$ cost of multiplying $(A[i] \cdots A[k-1])$ by $(A[k] \cdots A[j-1])$ for $k$ in range $(i+1, j))$

- $\mathrm{DP}[i, i+1]=0$
$\Longrightarrow$ cost per subproblem $=O(j-i)=O(n)$

4. topological order: increasing substring size. Total time $=O\left(n^{3}\right)$
5. original problem $=D P[0, n]$
(\& use parent pointers to recover parens.)
NOTE: Above DP is not shortest paths in the subproblem DAG! Two dependencies $\Longrightarrow$ not path!

## Edit Distance

Used for DNA comparison, diff, CVS/SVN/..., spellchecking (typos), plagiarism detection, etc.
Given two strings $x \& y$, what is the cheapest possible sequence of character edits (insert c , delete c , replace $\mathrm{c} \rightarrow \mathrm{c}^{\prime}$ ) to transform $x$ into $y$ ?

- cost of edit depends only on characters $c, c^{\prime}$
- for example in DNA, $\mathrm{C} \rightarrow \mathrm{G}$ common mutation $\Longrightarrow$ low cost
- cost of sequence $=$ sum of costs of edits
- If insert \& delete cost 1 , replace costs 0 , minimum edit distance equivalent to finding longest common subsequence. Note that a subsequence is sequential but not necessarily contiguous.
- for example H I E R O G L Y P H O L O G Y vs. M I C H A ELANGELO $\Longrightarrow$ HELLO

## Subproblems for multiple strings/sequences

- combine suffix/prefix/substring subproblems
- multiply state spaces
- still polynomial for $O(1)$ strings

## Edit Distance DP

(1) subproblems: $c(i, j)=\operatorname{edit-distance}(x[i:], y[j:])$ for $0 \leq i<|x|, 0 \leq j<|y|$ $\Longrightarrow \Theta(|x| \cdot|y|)$ subproblems
(2) guess whether, to turn $x$ into $y$, ( 3 choices):

- $x[i]$ deleted
- $y[j]$ inserted
- $x[i]$ replaced by $y[j]$
(3) recurrence: $c(i, j)=$ maximum of:
- $\operatorname{cost}($ delete $x[i])+c(i+1, j)$ if $i<|x|$,
- $\operatorname{cost}($ insert $y[j])+c(i, j+1)$ if $j<|y|$,
- $\operatorname{cost}($ replace $x[i] \rightarrow y[j])+c(i+1, j+1)$ if $i<|x| \& j<|y|$
base case: $c(|x|,|y|)=0$
$\Longrightarrow \Theta(1)$ time per subproblem
(4) topological order: DAG in 2D table:

- bottom-up OR right to left
- only need to keep last 2 rows/columns
$\Longrightarrow$ linear space
- total time $=\Theta(|x| \cdot|y|)$
(5) original problem: $c(0,0)$

## Knapsack:

Knapsack of size $S$ you want to pack

- item $i$ has integer size $s_{i}$ \& real value $v_{i}$
- goal: choose subset of items of maximum total value subject to total size $\leq S$

## First Attempt:

1. subproblem = value for suffix i: WRONG
2. guessing $=$ whether to include item $i \Longrightarrow \#$ choices $=2$
3. recurrence:

- $D P[i]=\max \left(D P[i+1], v_{i}+D P[i+1]\right.$ if $\left.\boldsymbol{s}_{i} \leqslant S ?!\right)$
- not enough information to know whether item $i$ fits - how much space is left? GUESS!

## Correct:

1. subproblem $=$ value for suffix $i$ :
given knapsack of size $X$
$\Longrightarrow \quad \#$ subproblems $=O(n S)$
2. recurrence:

- $D P[i, X]=\max \left(D P[i+1, X], v_{i}+D P\left[i+1, X-s_{i}\right]\right.$ if $\left.s_{i} \leq X\right)$
- $D P[n, X]=0$
$\Longrightarrow$ time per subproblem $=O(1)$

4. topological order: for $i$ in $n, \ldots, 0$ : for $X$ in $0, \ldots S$
total time $=O(n S)$
5. original problem $=D P[0, S]$
(\& use parent pointers to recover subset)
AMAZING: effectively trying all possible subsets! ... but is this actually fast?

## Polynomial time

Polynomial time $=$ polynomial in input size

- here $\Theta(n)$ if number $S$ fits in a word
- $O(n \lg S)$ in general
- $S$ is exponential in $\lg S$ (not polynomial)

## Pseudopolynomial Time

Pseudopolynomial time $=$ polynomial in the problem size AND the numbers (here: $S, s_{i}$ 's, $v_{i}$ 's) in input. $\Theta(n S)$ is pseudopolynomial.

Remember:
polynomial - GOOD
exponential - BAD
pseudopoly - SO SO
