

# CONTROLS ON AFRICAN CHANGE DURING THE PAST 34 MILLION YEARS

East Antarctic Ice Sheet: 34 Ma to now

West Antarctic and Greenland Ice Sheets: 14 Ma to now

Sea Level lowered at 34 Ma again at 14 Ma

Many Submarine Canyons initiated at 34 Ma

Pinning by Afar plume 31 Ma

Shallow Mantle convection set up 31 Ma). Persists today

Basins and Swells developing over shallow  
convection pattern from 31 Ma till now

Parts of Eastern Rift active 31 Ma till now

Zagros collision at 15 Ma

Western Rift active from 15 Ma till now

Arabia-Somali-Nubia plates distinct beginning ca 15 Ma

Climate changes: 34 Ma, 14 Ma. Indian ocean monsoon.

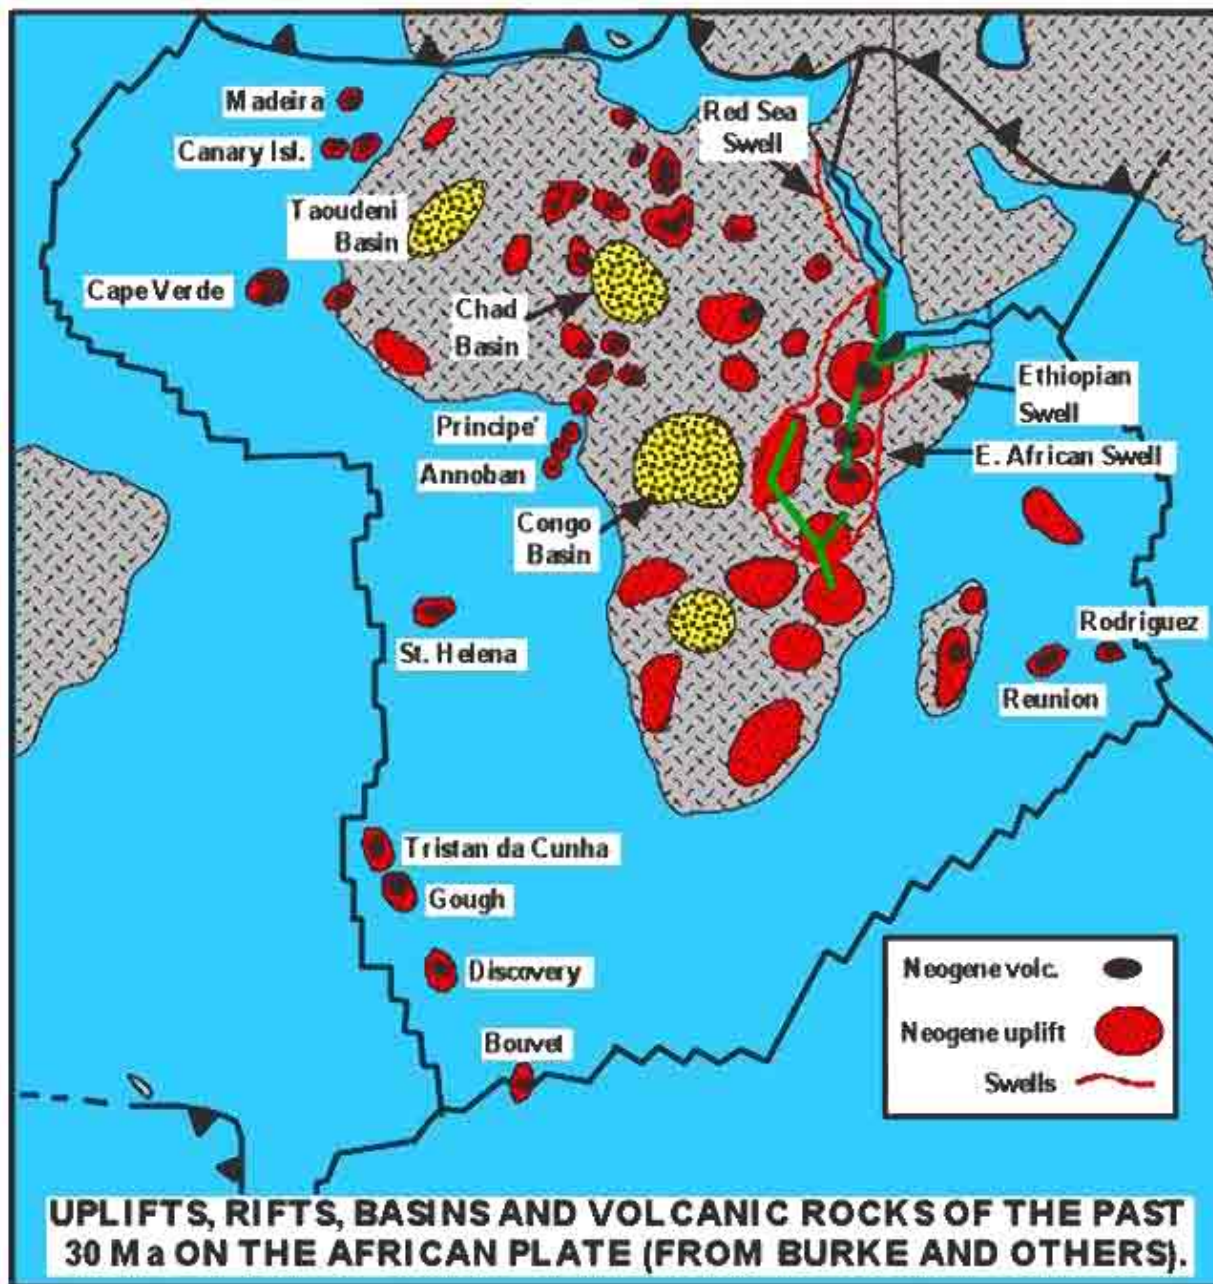

Oscillations since 3 Ma (Sahara) linked to northern  
hemisphere glaciations

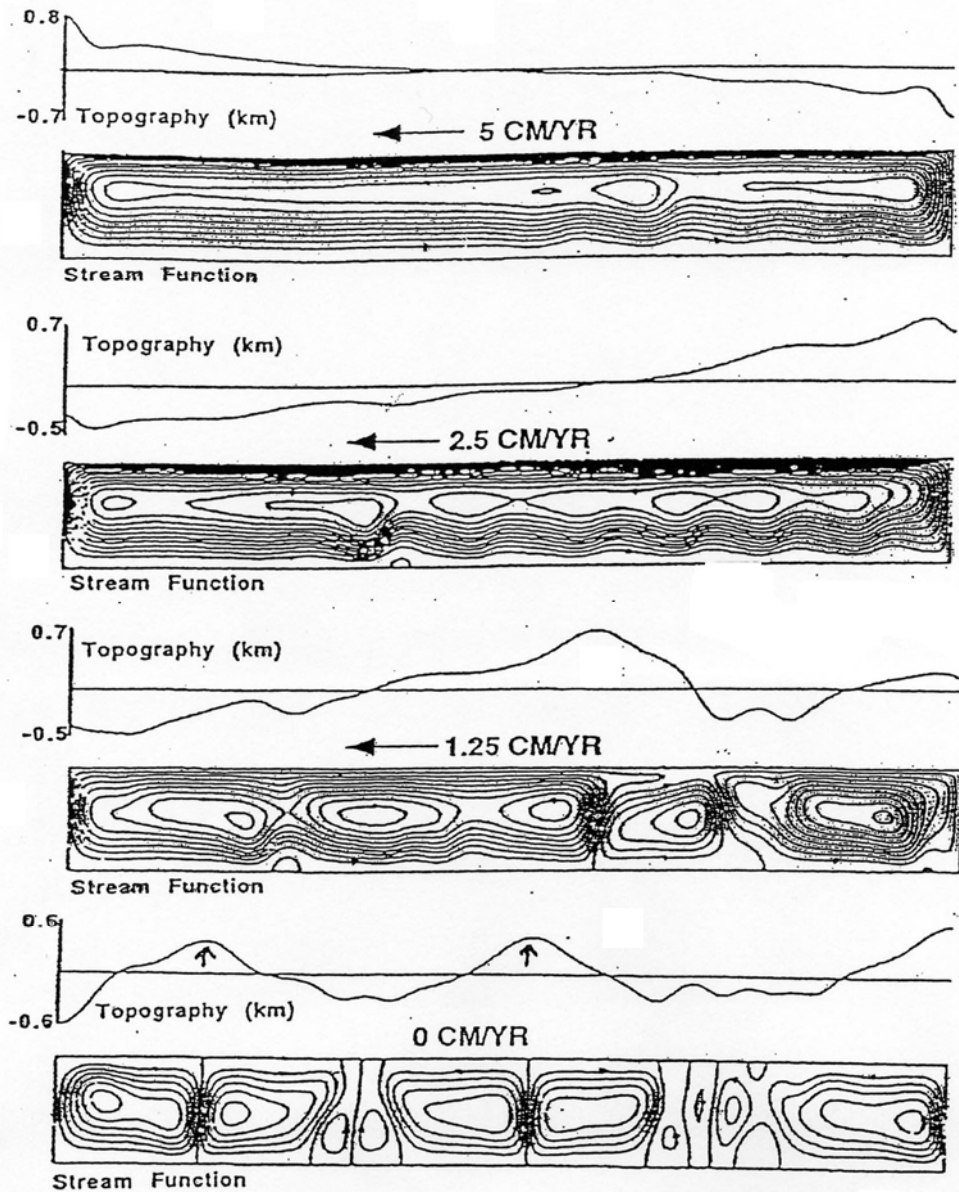

IMPINGEMENT OF THE AFAR PLUME ON THE BASE OF THE LITHOSPHERE  
STOPPED THE, ALREADY SLOW, ROTATION OF THE AFRICAN PLATE

- The Afar Plume raised the base of the lithosphere by  $h$  over  $\sim 1000\text{km}$  ( $h$  is only a few km,  $h'$  is even smaller)  $\sim 31\text{ Ma}$
- Ridge push no longer had sufficient energy to rotate the plate about the pole in the area of  $\sim 0^\circ$  Latitude  $\sim 0^\circ$  Longitude

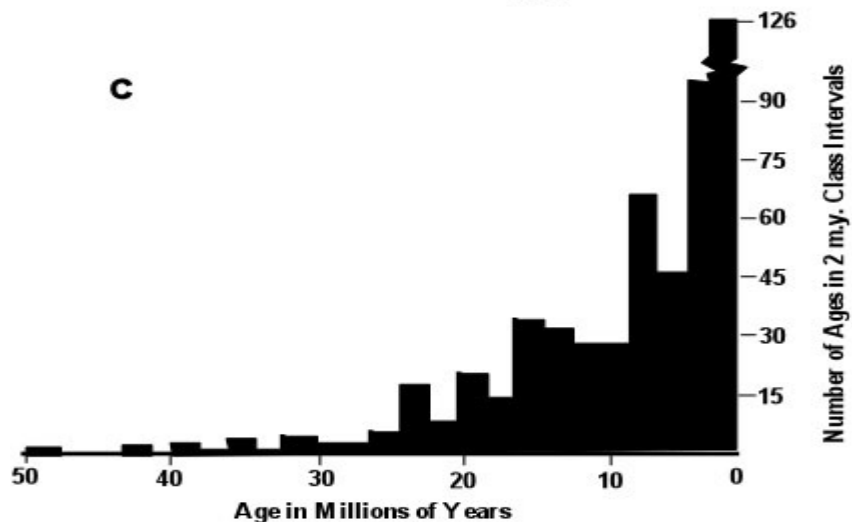

Results of numerical experiments by England & Houseman showing little relief on a plate moving over a shallow convecting mantle. Basins & Swells form only when the plate is at rest.

of London.

Published ages of igneous rocks on the African Continent showing an increase in activity at ca. 30 million years ago

Image courtesy of The Geological Society of South Africa.

Image courtesy of The Geological Society of South Africa.

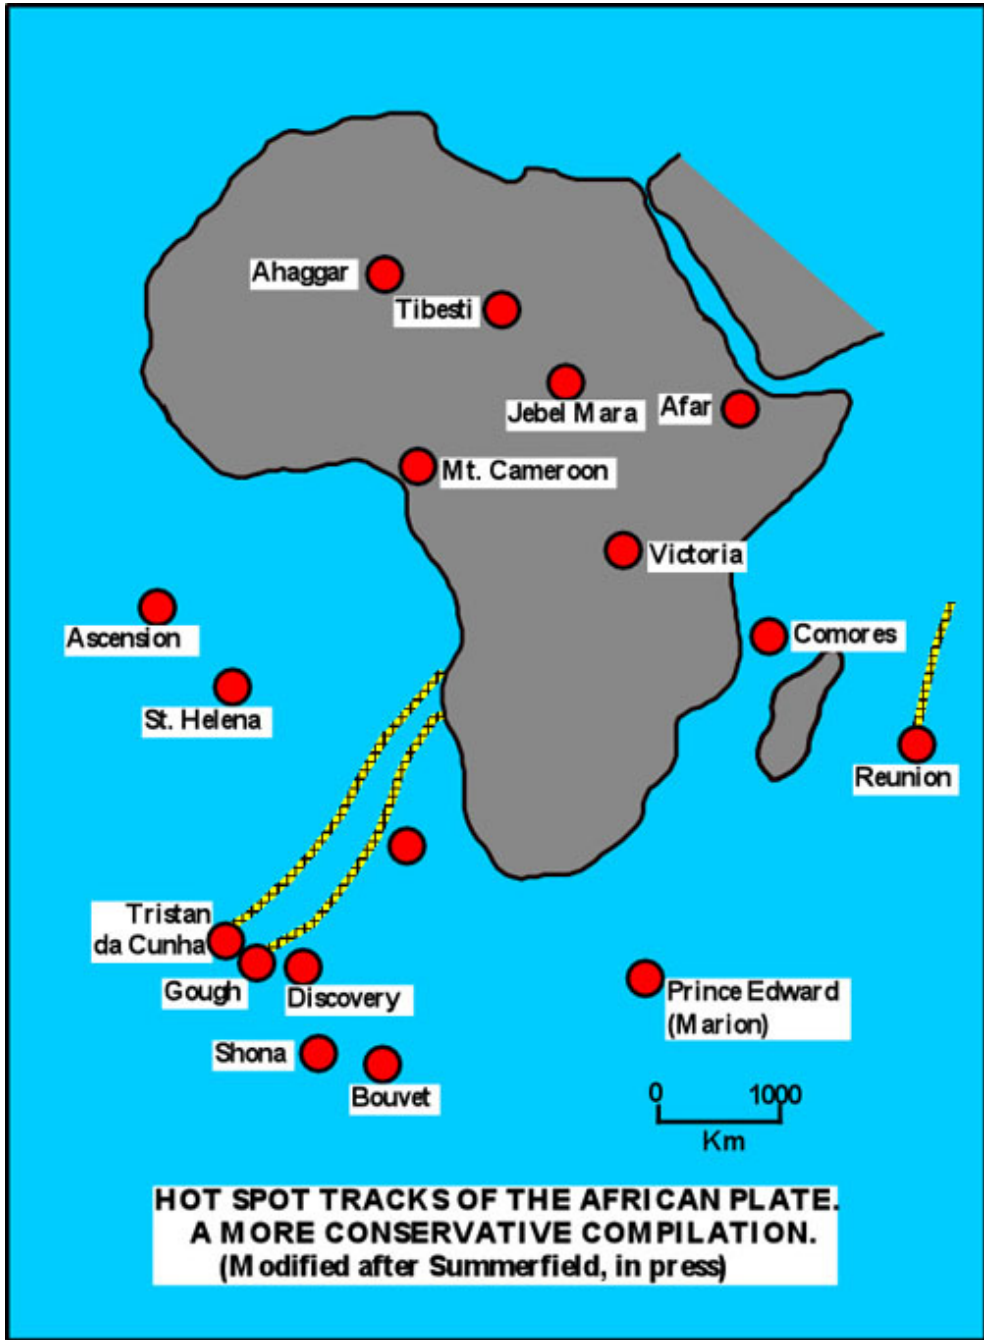

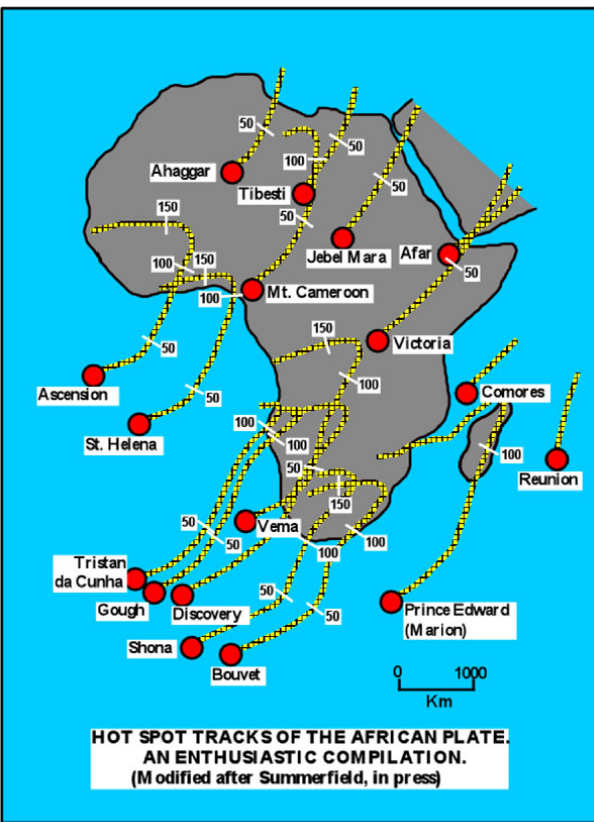

Volcanic rock ages from four places showing that activity has persisted in the same ca 200 km diameter areas for ca. 30 million years. More could have been plotted. Significant progression with a consistent azimuth has not been demonstrated.

Gripp & Gordon's 1990 sketch showing slowly moving Africa in a hot-spot reference frame over ca.3.7 Ma.

Since then slow relative motion of Nubian, Arabian and Somali plates over the same interval has been discerned .

Image courtesy of The Geological Society of South Africa.

Numerous hot-spot tracks have been reported from the African plate. Only the track of Tristan forming the Walvis Ridge stands up to scrutiny. Reunion is trackless.

At Dakar a  
shallow-sourced  
Mantle plume  
has been erupting  
for ca 25 My.  
basement is  
elevated but the  
“Mammelles”  
volcanoes are at  
sea level because  
the Senegal  
and Casamance  
Rivers have eroded  
the rising dome.  
Thick sediments eroded  
from what is now the  
Sahara are  
in deep water  
Offshore.

In the Ahaggar in the center of the Sahara a swell ca.1 M sq km in area has raised basement to ca.3 km asl in the past 30 My.

Volcanic rock volume, as is typical for the shallow-sourced mantle plume derived rocks of the African Plate, is very small.

Erosion of this swell carried a lot of sediment to the Niger delta before the Sahara desert first formed at ca.3 Ma.

The Jos plateau in Nigeria is a swell with 12 young crestal basaltic cones

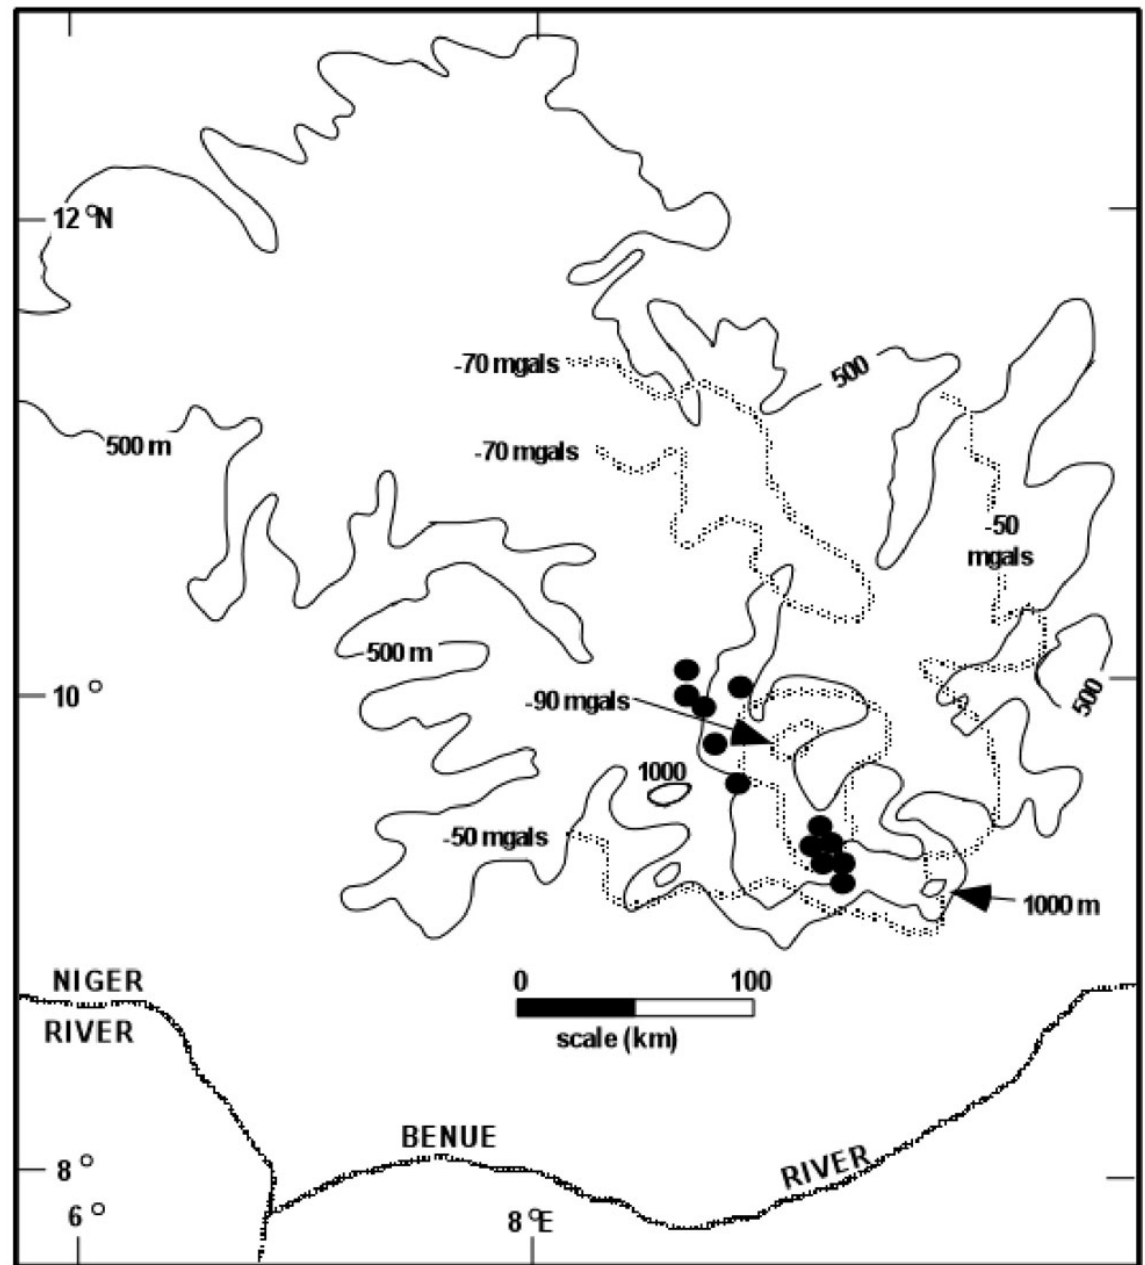

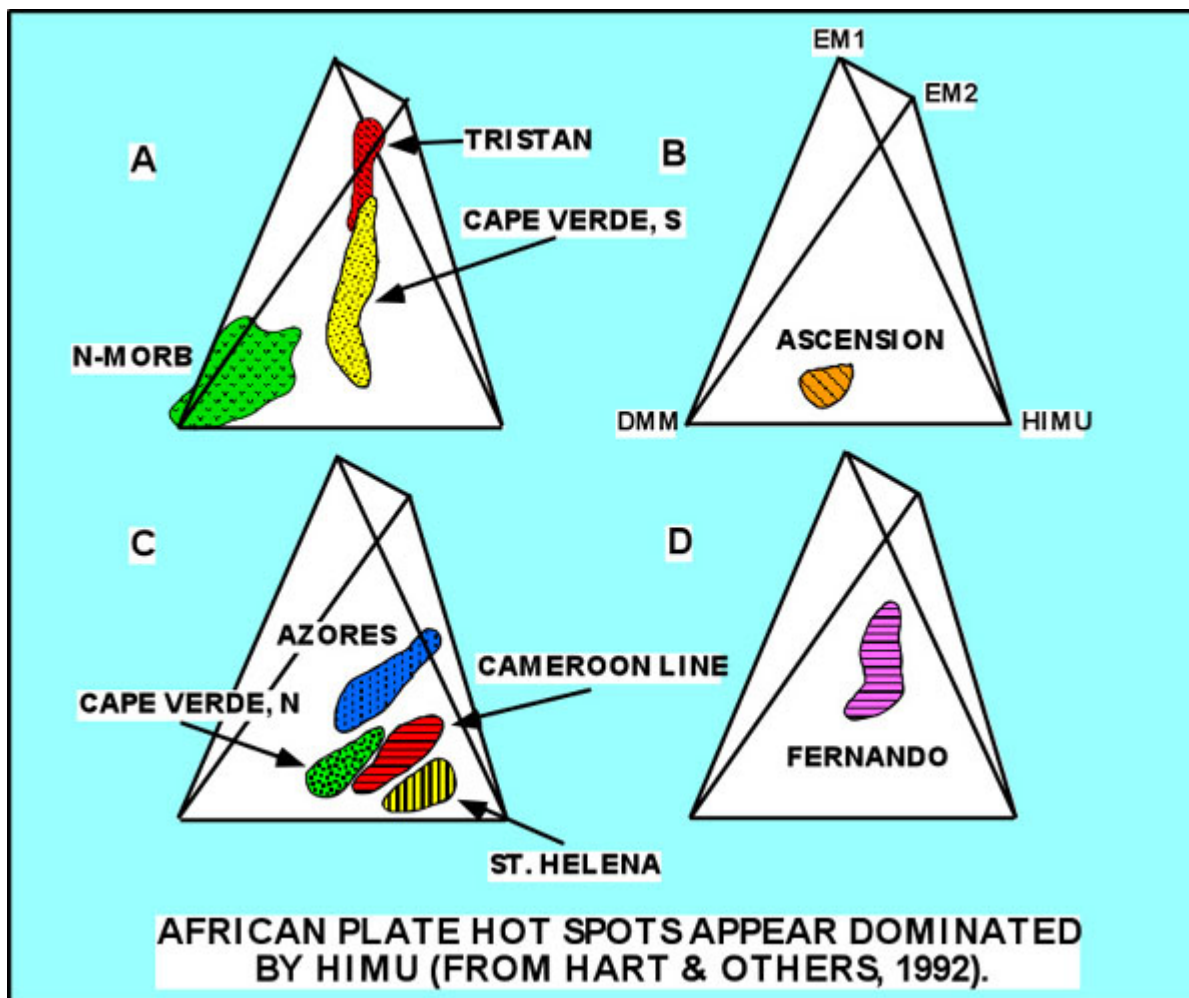

Image courtesy of The Geological Society of South Africa.

The Chad Basin is surrounded by 11 volcano-capped swells arranged in an ellipse.

Possibly this relates to a shallow-mantle convection pattern.
