

Very Large BWB Freighter

Fits Class VI Airports

Swing-Nose Loading

Aft Ramp Loading

**Payload Capacity:
68 Freight Containers**

Payload-Range Capability

Why Consider Formation Flight?

$$D_i = (1/\pi q e) (W/b)^2$$

- Two airplanes flying in proper formation will experience an induced drag reduction on the order of 50 percent, (assuming their combined spanload provides the same e as their individual spanloads).
- An airplane flying near the ground at a height on the order of 10 percent of its wingspan will experience an induced drag reduction on the order of 50 percent via an increase in $e > 1$.

Induced Drag Sensitivity to Lateral & Vertical Position

$$C_{Di} = (C_{L1}^2 + C_{L2}^2 + 2C_{L1}C_{L2}\sigma_1) / \pi AR$$

Figure 2. Variation in Mutual Induced Drag (σ_1) With Aircraft Position, Horseshoe Vortex Model.

Ref. Blake & Multhopp
*Design, Performance and
Modeling Considerations for
Close Formation Flight,*
AIAA-98-4343.

Rolling & Yawing Moment Sensitivity to Lateral & Vertical Position

$$\Delta C_{lk} = (2C_{Lj}/AR) \tau_{12} \quad \Delta C_{nk} = (C_{Lj} C_{Lk} / \pi AR) \tau_{12}$$

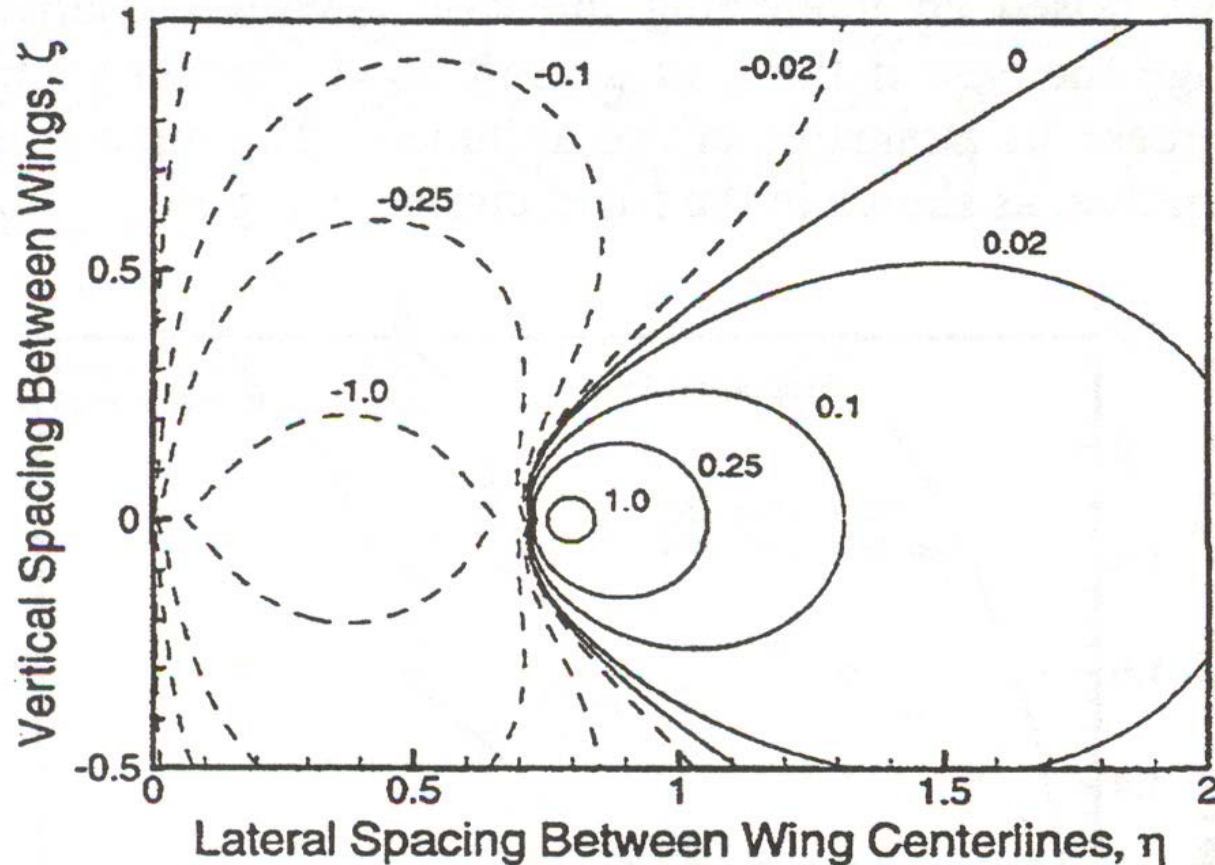

Figure 10. Variation in Rolling/Yawing Moment Factor τ_{12} With Aircraft Position, Horseshoe Vortex Model.

Design, Performance and Modeling Considerations for Close Formation Flight,
 AIAA-98-4343

Effect of Lateral Position on Range

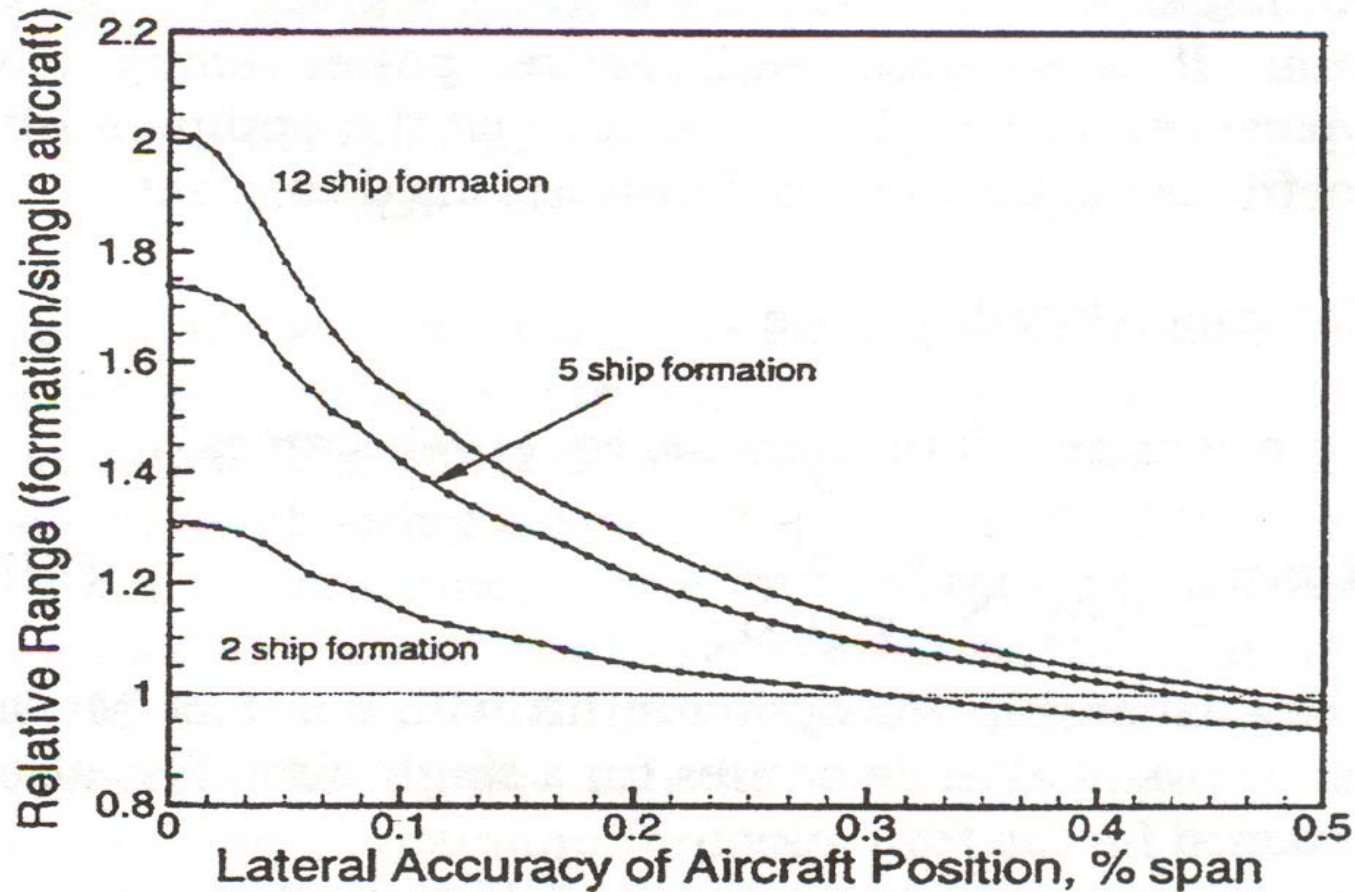

Figure 7. Effect of Lateral Position Accuracy Size on Relative Range. ($M=0.85$, 10 min rotation)

Ref. Blake & Multhopp, *Design, Performance and Modeling Considerations for Close Formation Flight*, AIAA-98-4343.

Example Spanload for Formation Flight

- Maximum L/D
- Trimmed in pitch and roll

Figure 3. Optimum load distribution $z/b=0.01$,
 $y/b=0.89$

Ref. Iglesias & Mason,
*Optimum Spanloads in
Formation Flight*, AIAA-
2002-0248

Optimum C_L Distribution for Minimum C_{Di}

Figure 5. Distribution of Lift Within Formation for Minimum Induced Drag, $\eta=0.85$, $\zeta=0$.

Ref. Blake & Multhopp, *Design, Performance and Modeling Considerations for Close Formation Flight*, AIAA-98-4343

Distribution of Power Reduction for 15-Plane Formation

e_{μ} = power reduction of individual airplane

$E = 0.23$ = power reduction of 15-airplane formation

Fig. 6: Distribution of flight power reduction in 45° swept V-shaped formations of $n = 15$ equal wings at spanwise distance $\Delta y = 0$ and $c_{Di} / c_{D0} = 0.5$ for various leading positions n_1 .
 Formation A = Oblique line, $n_1 = 1$
 Formation B = Unsymmetr. formation, $n_1 = 4$
 Formation C = Symmetrical formation, $n_1 = 8$.

Ref. Hummel, *The Use of Aircraft Wakes to Achieve Power Reductions in Formation Flight*, AGARD CP-584, 1996

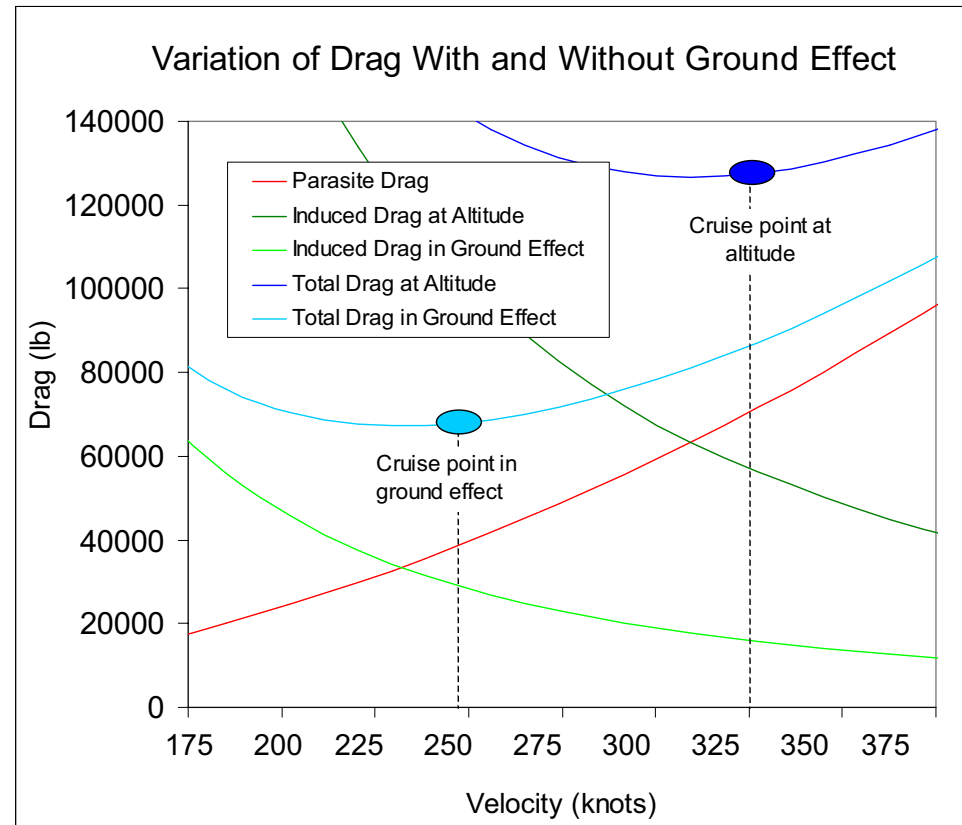

Ground Effect

- Ground effect provides a reduction in induced drag by reducing the downwash via $e > 1.0$
- Since density is fixed (sea level), this results in a lower optimum speed.

$$D = f_q + (1/\pi e q) (W/b)^2$$

The speed for L/D_{\max} is

$$V^2 = (2/\rho) (W/b) / (\pi e f)^{1/2}$$

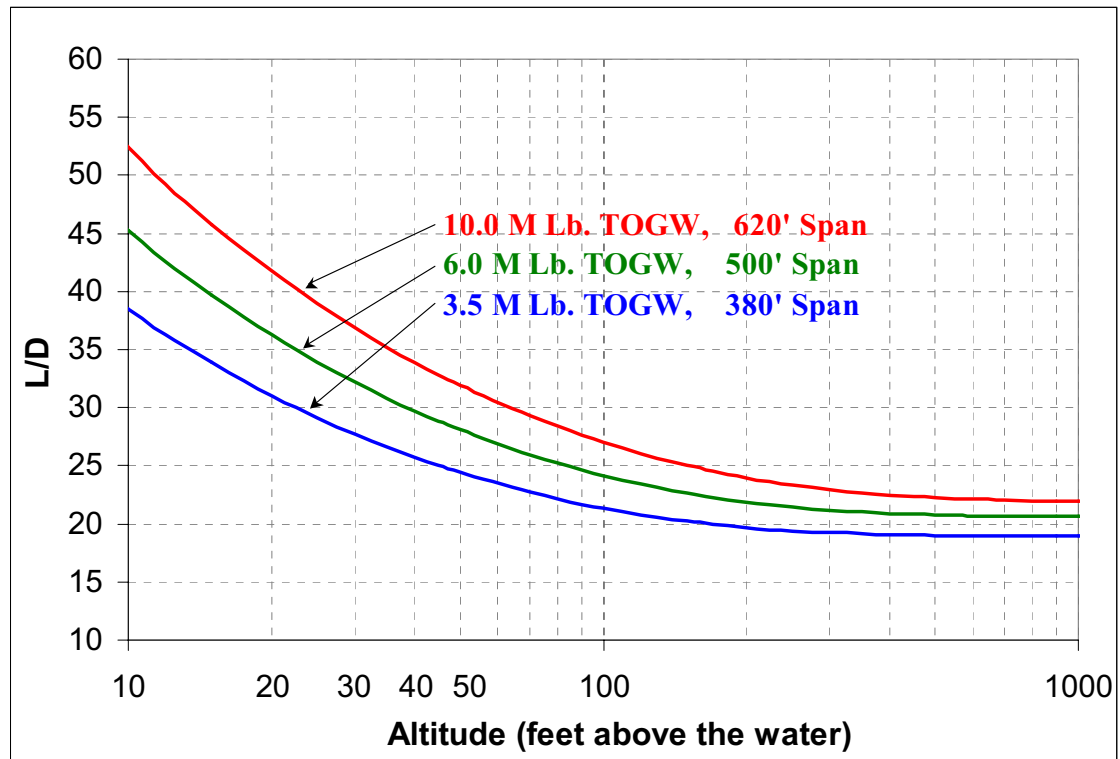

Ground effect flight reduces both induced and parasite drag force. Proximity to the ground suppresses wing downwash and reduces induced drag force. By slowing to a speed below the free-air optimum, parasite drag can be reduced more than induced drag is increased.

Airspeeds for the Pelican are chosen at points slightly faster than optimum both in and out of ground effect to improve productivity at a very small cost to efficiency.

Preliminary inviscid computational fluid dynamics analysis has not revealed significant aerodynamic shortcomings in the configuration.

Lift to Drag Ratio

- L/D depends on size and height above ground surface
- Increased size improves ground effect, wetted aspect ratio and Reynolds number
- L/D improves powerfully with reduced height

Autonomous Flight

Conceptual Development Plan

- **Primary goals: formation flight & reduced flight crew**
- Start with single-pilot operation with autonomous backup leading up to fully autonomous operation and autonomous station-keeping
- Technology development
 - Build on current UAV efforts
 - FAA involvement at beginning
 - Regulation development concurrent with system development
 - Certification demonstration requirements
 - Complete operational system simulation
 - Demonstration flight test program
 - Utilize existing UAV autonomous flight experience
 - System demonstration using generic transport aircraft
- Autonomous flight certification
 - Initial certification with generic transport aircraft
 - Initially over water and avoid population centers

Autonomous Flight

Conceptual Objectives/Requirements

1. Single pilot operation with autonomous backup

2. Fully autonomous operation

- Operate out of existing airports
- Operate in existing controlled airspace
- Flight monitoring/ATC communication from ground station by non-pilot operator(s)
- Autonomous ground operation (takeoff, landing, taxi)

Autonomous Flight

Conceptual System Elements

- Ground station with human flight monitor/controller and two-way ATC communications
- Satellite link between ground station and aircraft
- Pre-programmed flight plan with GPS way-points
- Differential GPS for terminal operations
- Cockpit view high-res video for terminal/landing operations

Airplane Design for Formation Flight

- Autonomous station-keeping
 - direct side force desirable
- Adjustable span-load for trim & efficiency in and out of formation flight mode
- Design-trade issues
 - Optimum span-load for free flight is “triangular”, with a significantly lighter loading at the wing tips than elliptic. This reduces the wing root bending moment, and hence the structural weight.
 - The optimum span-load for formation flight has an unusually high load outboard (well beyond elliptic), and it is asymmetric.
 - Ride quality for downstream formation members could be critical for passenger applications.

Design for Formation Flight (cont.)

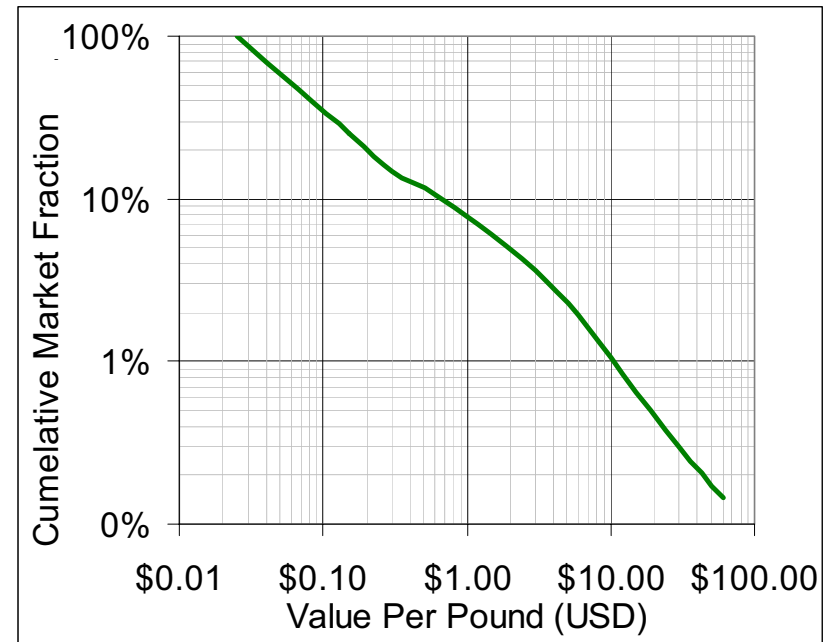

- The reduction of induced drag occurs via an increase in effective wingspan.
- Maximum L/D occurs when profile drag equals induced drag, and profile drag does not change with formation flight.
- Thus maximum L/D must be achieved by flying at a correspondingly higher lift coefficient when in the formation mode.

Dedicated Freighter vs Adapted Military or Commercial Airplane

- Airplane price
 - non-recurring & recurring cost
- Utilization
 - freighter 5 hrs/day, commercial airliner 14 hrs/day
- Efficiency
 - \$/ton-mile cash-related operating cost
- Freighter-unique capability
 - e.g. out-sized payload, very large airplane
- Future requirements and unknowns
 - airplanes last 30 to 50 years
- To date, a dedicated freighter business case has not closed

Market - Size

- Total cargo market in 2020 is approximately 70 Trillion ton-miles per year
 - Capacity of 250,000 747-400's
- Market fraction can be estimated on the basis of cargo value per pound
 - 25% of market worth > \$0.10/lb
 - 8% of market worth > \$1.00/lb
 - 1% of market worth > \$10.00/lb
- Combined with Total Distribution Cost analysis, this data can provide rough order of magnitude market size estimate

Major Operating Cost Fractions Have Changed

- Need for increased utilization of airplanes
 - drives modular design
- Cost of ownership has become the major element of operating cost

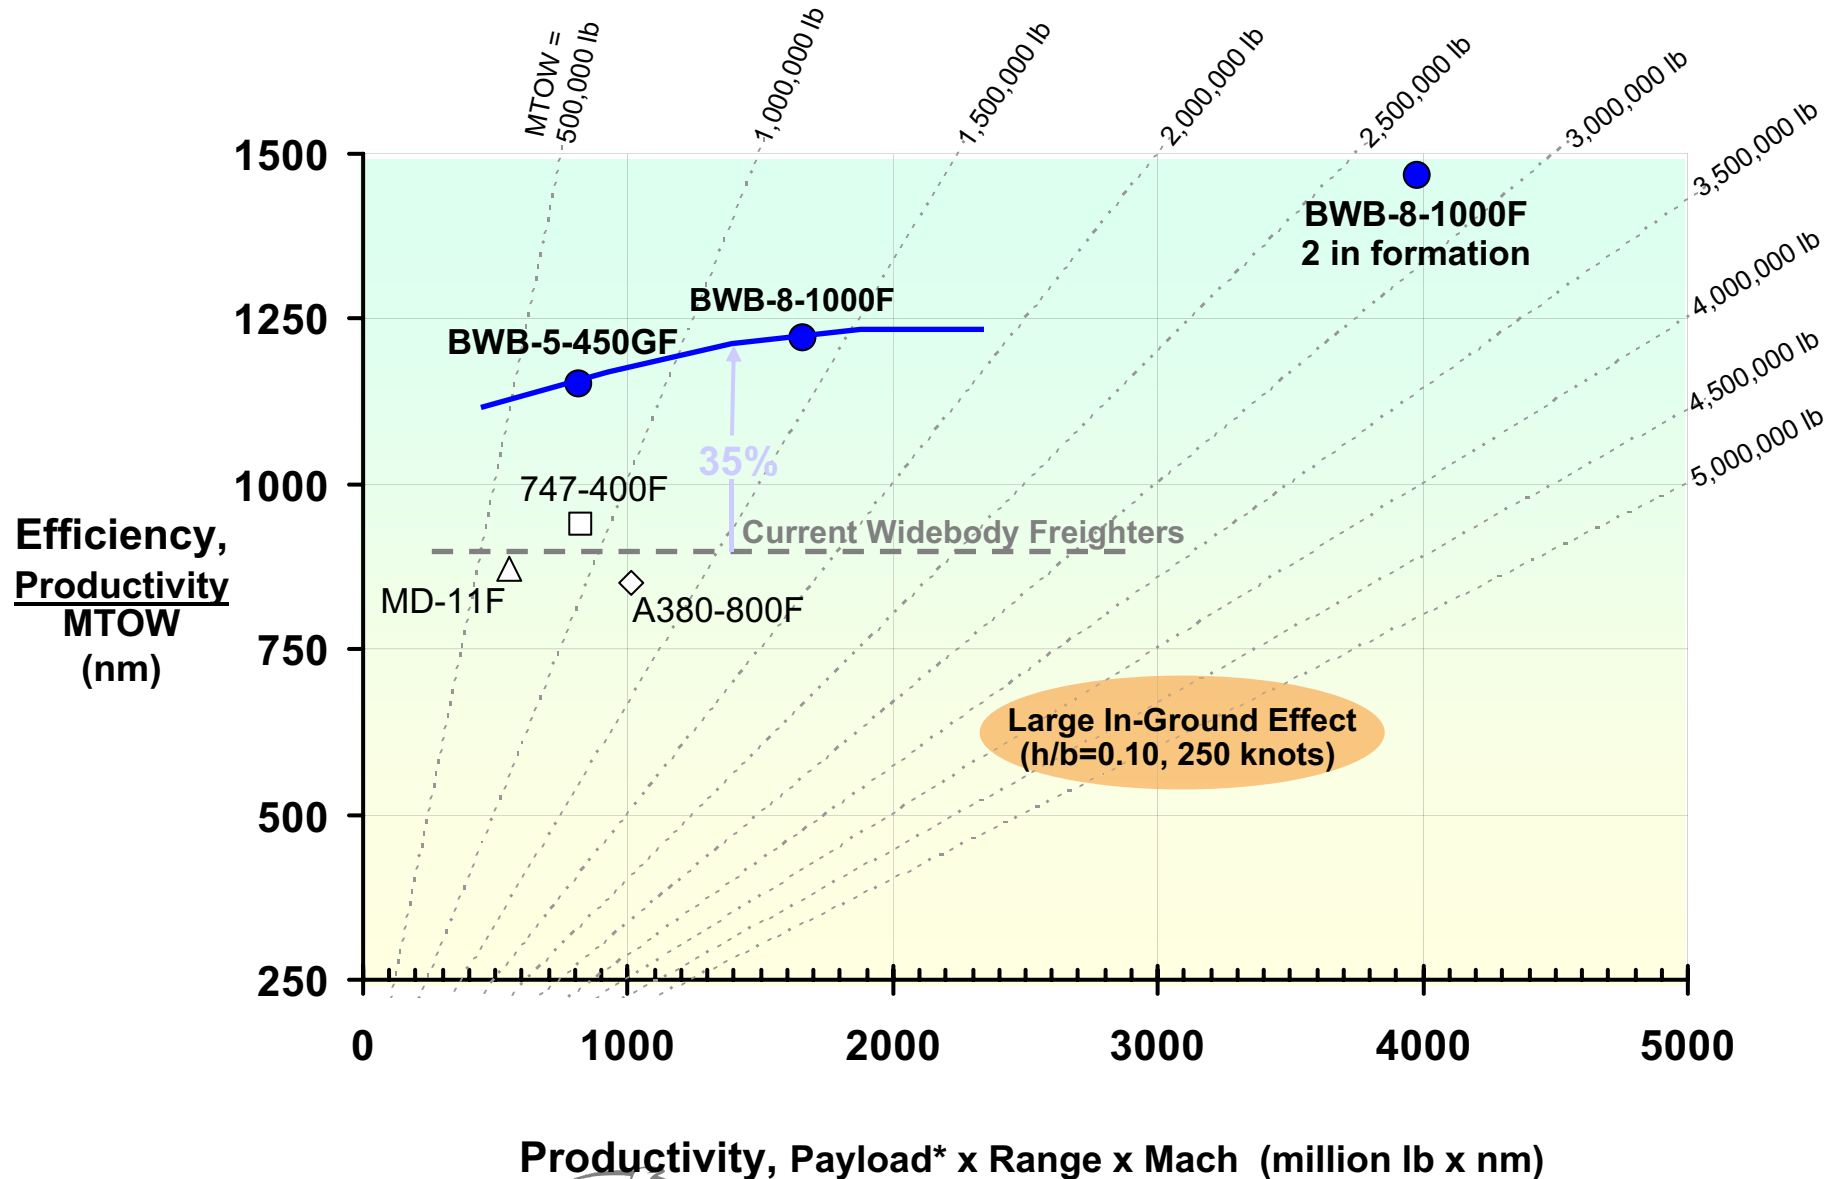

Past

Present

Freighter Efficiency vs Productivity

Cargo Delivery Schedule/Cost Assumptions

Current Boeing OPCOST Model

| | | | | |
|-----------------------------|---------------|--------|--------------|---------------------|
| Drop off package at airport | Load on plane | Fly | Unload plane | Airport destination |
| | x hrs | 6¾ hrs | x hrs | Total: 7+ hrs |
| Costs: | | | | |

Boeing OPCOST economics includes:

- Fly
- Load & unload plane
- Cargo Commissions
- Advertising & Publicity
- Reservations & Sales
- General & Administrative

Today's FedEx Package Delivery

| | | | | | | | | |
|-------------------------------------|-------|--------------------------------------|-------|--------------------------------------|-------|--------------------------------------|-------|-------------------------|
| Drop off package at pickup location | Truck | Unload truck, sort and load on plane | Fly | Unload plane, sort and load on plane | Fly | Unload plane, sort and load on truck | Truck | Drop off at destination |
| | 2 hrs | 2 hrs | 3 hrs | 3 hrs | 3 hrs | 2 hrs | 3 hrs | Total: 18 hrs |
| Costs: | | | | | | | | |

Ships

| | | | | | | |
|--|--------|--|---------|--|--------|-----------------------------|
| Pick up ISO at shipper and load on truck | Truck | Unload ISO from truck, sort and load on ship | Sail | Unload ISO from ship, sort and load on truck | Truck | Drop off ISO at destination |
| | 3 days | 7 days | 10 days | 7 days | 3 days | Total: 30 days |
| Costs: | | | | | | |

Catalina Delivery Concept

| | | | | | | |
|--|-------|-----------------------------------|--------|---|-------|-----------------------------------|
| Pick up container at shipper and load on truck | Truck | Unload truck and load on Catalina | Fly | Unload Catalina, sort and load on truck | Truck | Drop off container at destination |
| | 2 hrs | 2 hrs | 10 hrs | 2 hrs | 3 hrs | Total: 19 hrs |
| Costs: | | | | | | |
