## HW\# 2 Solution Set

## Problem 1: (10 points)

a. (3 points) Three points for something feasible (actually anything will do here). 1 point for something useful or convincing.
b. (4 points) One point for description, two for spatial and temporal scales, and one for expected results.
c. (3 points) Three points for cost.

## Problem 2: (10 points)

a. (2 points) The deepest part of the ocean is The Marianas Trench between 10,911 $\boldsymbol{m}$ (Kaiko March $24^{\text {th }}, 1995$ ), which is the most accurate reading. Other reports are deeper by as much as $11,040.04$. As a comparison Mt. Everest is 8444.43 m high. Located at approximately $11^{\circ} 19^{\prime} N$ latitude and $14215^{\prime} E$ longitude, in the Pacific Ocean.
b. (2 points) $1^{0}$ latitude $=111 \mathbf{k m} .1^{0}$ longitude $=111$ cosine (latitude) $\mathbf{k m} . \operatorname{Pg} 21$ ST.
c. (3 points) The speed of sound in water is a function of temperature, depth, and salinity. Pg 35 ST .
d. (3 points) From Pg 35 ST. If the speed of sound is plotted as a function of depth there is usually a minimum around 1000 m . The depth of minimum sound speed is the sound channel. A sound channel can carry sound up to $10,000 \mathrm{~km}$ away. It occurs in all oceans, and it usually reaches the surface at higher latitudes. In the sound channel sound can travel very far, sometimes half way around the earth. Sound rays that begin to travel outside the channel are directed back to the sound channel. I like to think of it as a large fiber optic cable for sound.

## Problem 3: (10 points)

a. ( 2 points) The Pacific (according to Google Earth) along the equator lies at $80^{\circ} 6^{\prime}$ 34 W and $103^{\circ} 48^{\prime} 46 \mathrm{E}$, which is 19565 km or 12157.6 miles ( $\left.\sim 183^{\circ} 54^{\prime}\right)$. This is an assumption that the earth is generally spherical and uses google earth.
b. (2 points) Google Earth.
c. (2 points) The accuracy is down to the sub second according to google. I trust it to the second, which is much better than the degree accuracy we are looking for. Of course the South American landing of the reading is very close to a river delta and could be growing or shrinking by some amount each year!
d. (2 points) I have a good feeling that this is within $1^{\circ}$ of accuracy, because I was able to get sub second resolution using google earth. I gave everyone points for being close.
e. (2 points) They go north because that happens to be the shortest route. If you could place a string on the earth from one point to another and pull it taught you would see that the shortest distance to Tokyo from LA is to head north for a while and then turn south.
a. (2 points) The sky is blue because the atmosphere scatters shorter frequency wavelengths (ie blue, violet), but lets wavelengths that are longer (reds, oranges, yellows) through with little or no scattering. (Wikipedia)
b. (2 points) The sky near the horizon is much thicker than above. Therefore, in the daytime the light near the horizon tends to be paler than above. In the evening as the sunsets the sunlight appears even redder because the remaining wavelengths (longer) are filtered even further, thus filtering almost all the blues and greens leaving a very orange or red Sun. The scattering effect is known as Rayleigh law. (Wikipedia)
c. (2 points) $\mathrm{C}=\lambda * \mathrm{f}$ (wave speed $=$ wavelength * frequency)
d. $(2$ points $)$ Blue light $=430-500 \mathrm{~nm}$, Green light $=520-565 \mathrm{~nm}$, Red light $=625-$ 740 nm .
e. (2 points) Blue light ( $\sim 430 \mathrm{~nm}$ ) propagates furthest in water because it is the least absorbed.

## Problem 5: (10 points)

a. (5 points) The direction of the winds is from the high-pressure zone to the lowpressure zones. The $30^{\circ} \mathrm{N}$ and $30^{\circ} \mathrm{S}$ high-pressure regions blow towards the equator. The equatorial region tends to blow towards the west because of the converging winds from the north and south. Pg. 41 ST.
b. (5 points) The highest evaporation occurs around the $30^{\circ} \mathrm{N}$ and $30^{\circ} \mathrm{S}$ latitudes. The equatorial region has heavy precipitation. Pg. 41 ST.

## Problem 6: (10 points)

a. (4 points) In general, the warmest surface temperatures are found at the equator $\sim 30^{\circ} \mathrm{C}$. The heat gradually dissipates to $\sim 23^{\circ} \mathrm{C}$ near the $30^{\circ} \mathrm{N}$ and $30^{\circ} \mathrm{S}$ longitude lines. Near the poles have the coldest surface temperatures $-1^{\circ} \mathrm{C}$. The moderate temperatures $\left(23^{\circ} \mathrm{C}-10^{\circ} \mathrm{C}\right)$ occur between $30^{\circ} \mathrm{N}$ and $\sim 55^{\circ} \mathrm{N}$ in the north and $30^{\circ} \mathrm{S}$ to $55^{\circ} \mathrm{S}$. The rest of the water is cold toward the poles and varies from $10^{\circ} \mathrm{C}$ to $1^{\circ} \mathrm{C}$. There are irregularities to this trend. In the Pacific along the equator near Equador has colder water below $23^{\circ} \mathrm{C}$ and extends from the coast $\sim 10^{\circ}$ longitude. The Pacific coast of South America and the Atlantic coast of Africa are $10^{\circ}$ colder than the rest of the ocean at that latitude. There is also a $10^{\circ}$ cooler region along the pacific coast of America and Atlantic coast Europe. Together these regions narrow the warm surface temperatures region found at the higher latitudes. The western Pacific is warmer on average than the eastern portion. The Indian ocean is dominated by $30^{\circ} \mathrm{C}$ temperatures.
b. (4 points) The main cause of the ocean surface temperature is the sun. The sun heats the water through isolation. The ocean releases heat in the form of radiation. The average temperature of the sea relates to the intensity of the sunlight at that region. The sun reaches the earth most directly at the equator with decreasing angles of incidence at the increasing latitudes. In general, this assumption is valid. The irregularities are due to wind driven currents and separately from deep waters coming to the surface. For instance, along the equator the winds are typically westerly. This causes the warm waters along the Western coast of the Americas to move eastward. To replace the movement of
those warm waters the cooler waters from higher latitudes move into those regions. They are of course heated but the cooler regions causes the narrowing of the warm band along both the western coast of the Americas and the western coast of Africa and Europe. The strange cold surface temperature off the coast of Equador may be explained as some upwelling of a cooler water from the deeper sea.
c. (4 points) The simplest model is to say that the water temperature is linear decline of $30^{\circ} \mathrm{C}$ at $0^{\circ}$ latitude to $24^{\circ} \mathrm{C}$ at $30^{\circ} \mathrm{N}$ and $30^{\circ} \mathrm{S}$. Then taking another linear fit from $24^{\circ} \mathrm{C}$ at $30^{\circ} \mathrm{N}$ and $30^{\circ} \mathrm{S}$ to $-1^{\circ}$ at $90^{\circ} \mathrm{N}$ and $90^{\circ} \mathrm{S}$. This is a very crude model but in general works against the data. In general the sun affects the surface temperature directly, which can vary if winds and currents are strong enough or persistent enough throughout the year. If you proposed a model that seemed reasonable I gave you full points. If you actually came up with an equation you get kudos.

## Problem 7: (10 points)

Full points for mentioning your interests in this course.
