

# **3.320/SMA5107: Lecture 9b (3/3/05)**

*Applications and Performance of DFT  
methods*

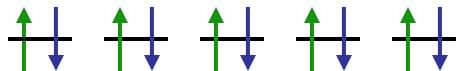

# Spin Polarization: The Local Spin Density Approximation (LSDA)

- Electrons have spin +(-)  $1/2 \mu_B$
- Spin is treated as a scalar quantity (this is approximate, as relation to angular momentum makes it a vector quantity)
- Two spin states often referred to as “up” $\uparrow$  and “down” $\downarrow$
- Up-Up interaction is different from Up-Down

# Exchange Effects: Refresher

Hund's rule: A consequence of Pauling exclusion principle

e.g. for atomic d-levels

Even in solids where energy levels are split, can get parallel filling if splitting is not too large

Why is this important ?

Filling of different orbitals  
may give the atom different  
chemical properties

Materials can carry a magnetic moment

$$\rho_{\uparrow} \neq \rho_{\downarrow}$$

# Spins in Density Functional Theory

In principle  $E_{xc}[\rho]$  “knows” about this effect, but in practice it is poorly approximated since only total charge density is variable

But in practice, need to help LDA along ...

Solution: Treat up and down densities separately

# Local Spin Density (LSD) = LDA with different charge density for up and down electrons

$$v_{eff}^{\uparrow} = v(r) + \int \frac{\rho(r')}{|r - r'|} dr' + \frac{\partial E_{xc}}{\partial \rho^{\uparrow}} [\rho^{\uparrow}, \rho^{\downarrow}]$$

$$v_{eff}^{\downarrow} = v(r) + \int \frac{\rho(r')}{|r - r'|} dr' + \frac{\partial E_{xc}}{\partial \rho^{\downarrow}} [\rho^{\uparrow}, \rho^{\downarrow}]$$

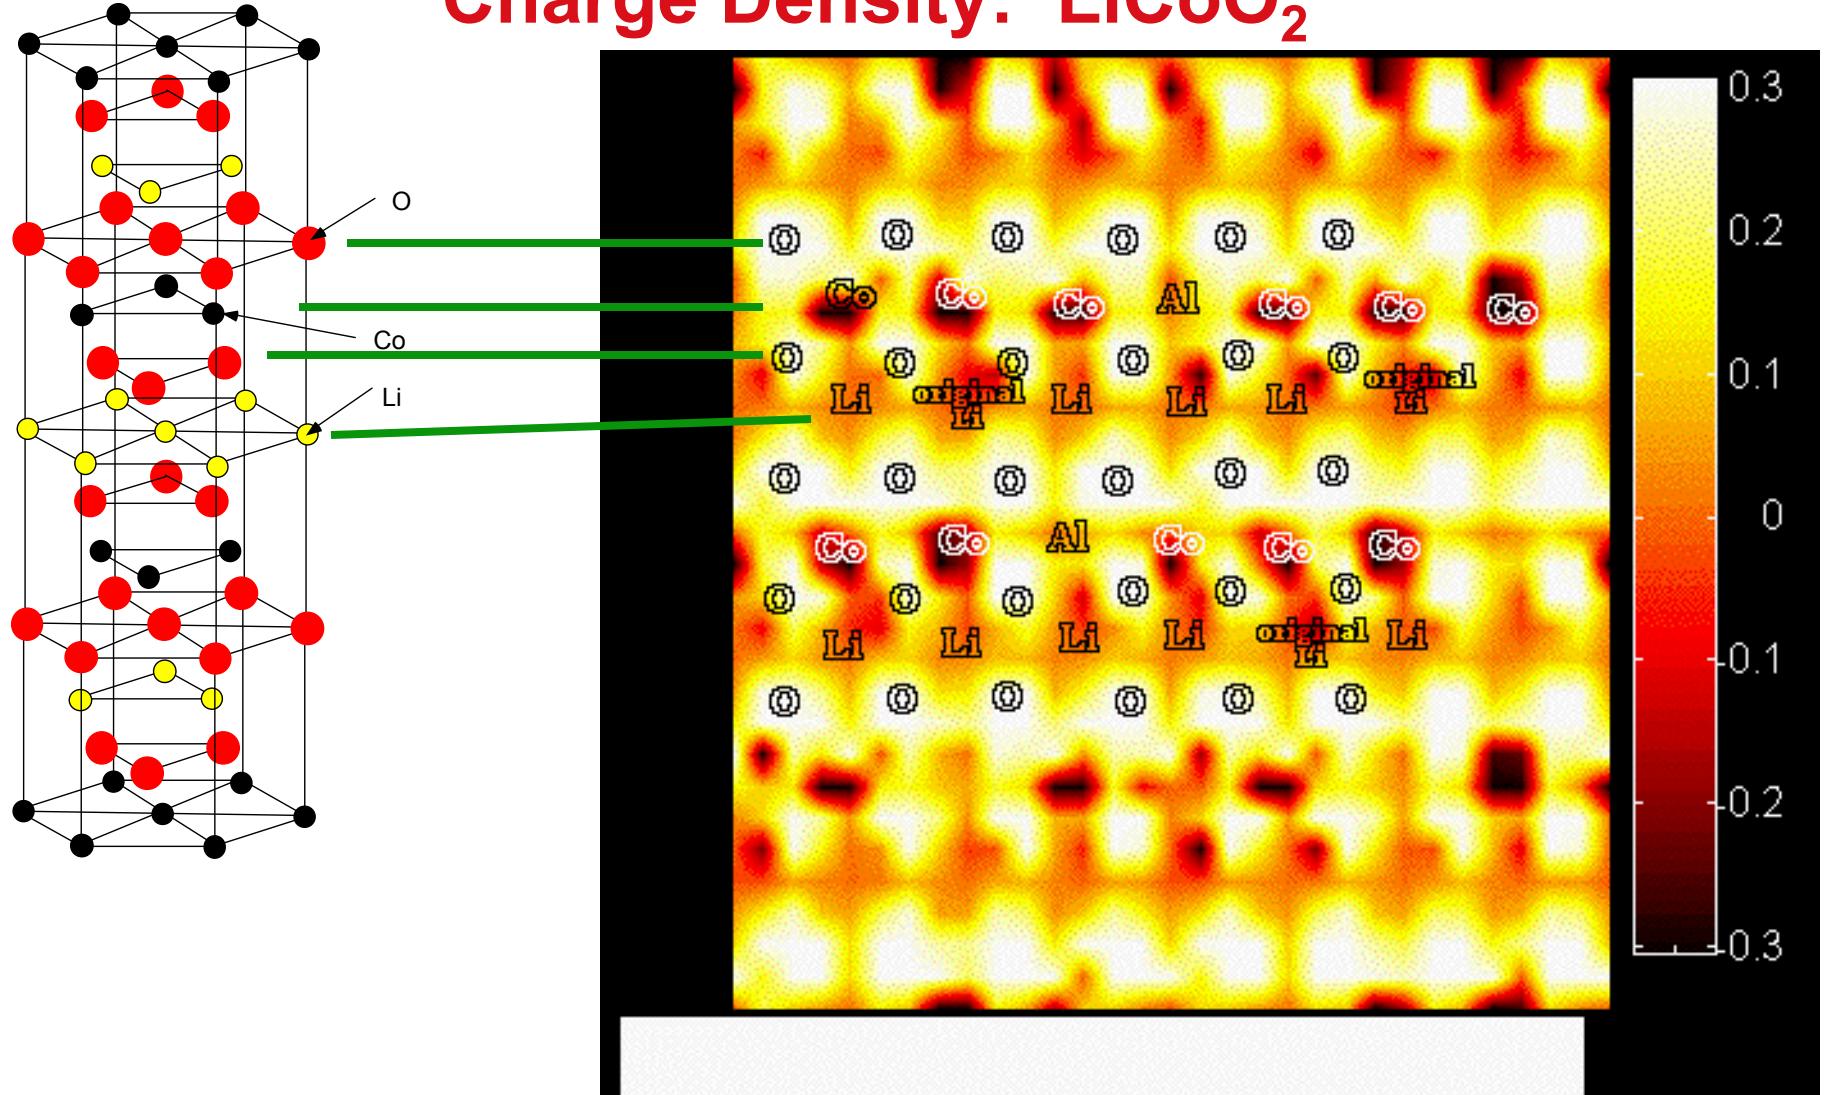

Up and down charge density can be different  $\rho_{\uparrow} \neq \rho_{\downarrow}$

Similar to restricted and unrestricted Hartree Fock

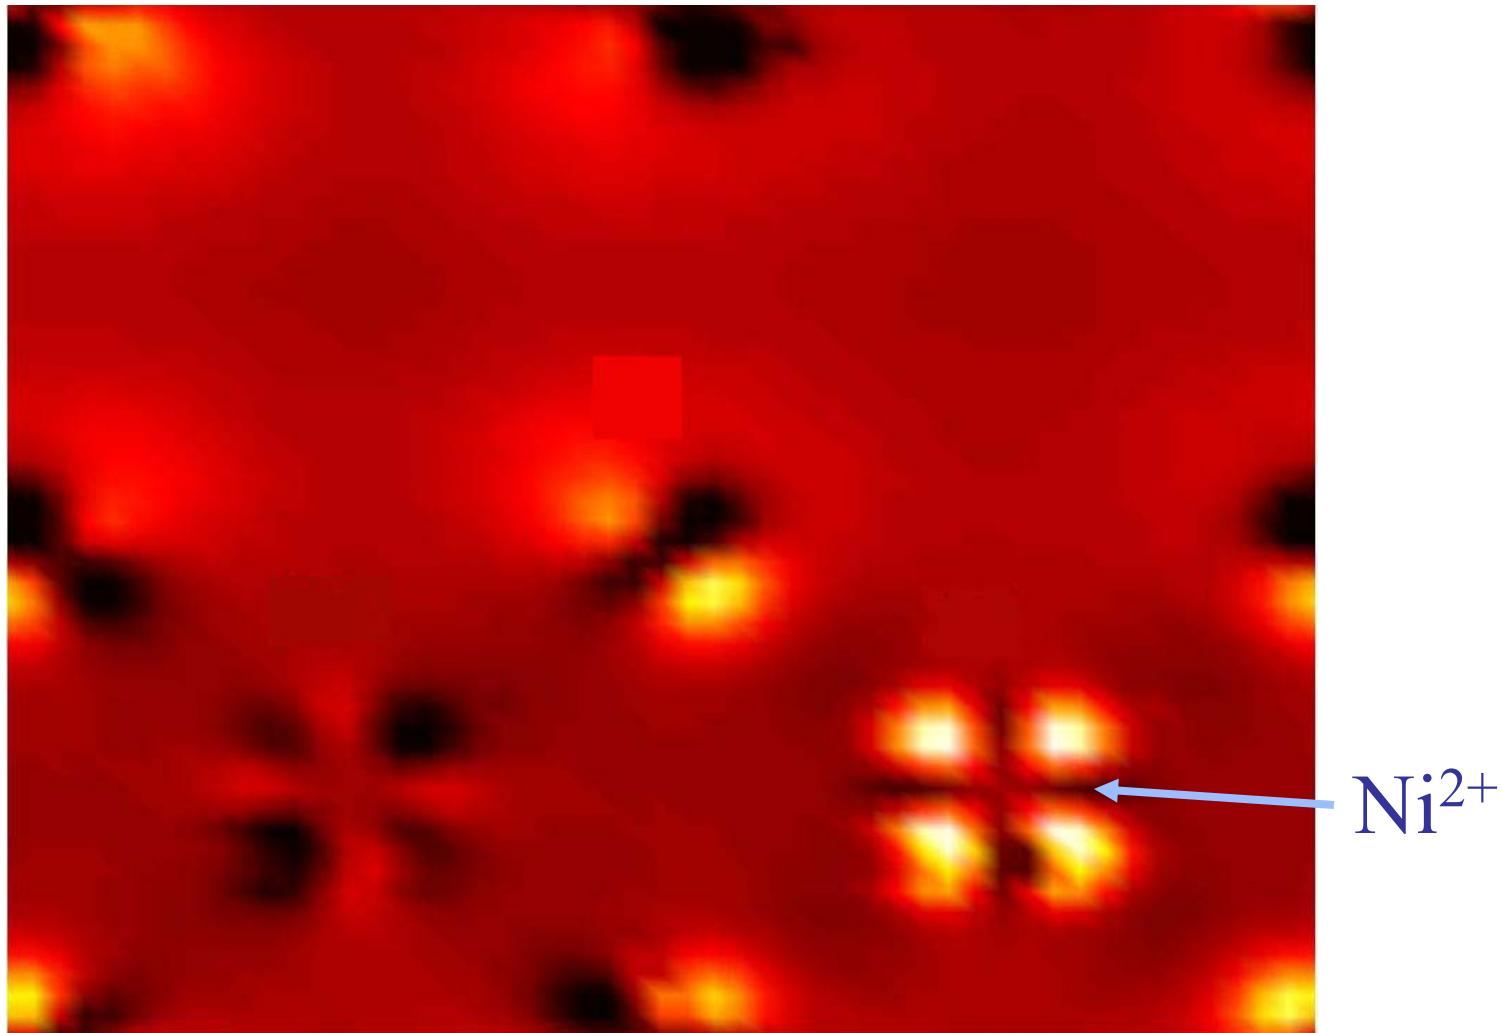

Regular LDA can not capture exchange effect well since it is non-local

A spin-polarized version of GGA exists as well

## Charge Density: LiCoO<sub>2</sub>

**Spin Density:** filters out unpolarized ions (e.g.  $O^{2-}$  )

# How good is the output from LDA/GGA ?

Computational quantum mechanics provides very basic information: Energy, charge density, band structure, optimized atomic positions, etc.

*How do I make a faster car from this ?*

Photo of sports car removed  
for copyright reasons.

First evaluate accuracy of basic information  
-> then understands how that propagates  
into higher order models

# Energies of Atoms

energy in Ry	<b>Li</b>	<b>Be</b>	<b>B</b>	<b>C</b>	<b>N</b>	<b>O</b>	<b>F</b>	<b>Ne</b>
<b>GGA: PW91</b>	214.928	229.296	249.24	275.561	2108.926	2149.997	2199.433	2257.893
<b>LDA</b>	214.668	228.892	248.686	274.849	2108.045	2148.939	2198.189	2256.455
<b>Expt.</b>	214.958	229.334	249.308	275.688	2109.174	2150.126	2199.45	2257.856
energy in Ry	<b>Na</b>	<b>Mg</b>	<b>Al</b>	<b>Si</b>	<b>P</b>	<b>S</b>	<b>Cl</b>	<b>Ar</b>
<b>GGA: PW91</b>	2324.514	2400.12	2484.686	2578.669	2682.386	2796.152	2920.278	21055.077
<b>LDA</b>	2322.867	2398.265	2482.618	2576.384	2679.88	2793.419	2917.313	21051.876
<b>Expt.</b>	2324.49	2400.086	2484.672	2578.696	2682.764	2796.2	2920.298	21055.098
energy in Ry	<b>K</b>	<b>Ca</b>	<b>Ga</b>	<b>Ge</b>	<b>As</b>	<b>Se</b>	<b>Br</b>	<b>Kr</b>
<b>GGA: PW91</b>	21199.825	21355.144	23850.018	24154.2	24471.917	24803.334	25148.619	25507.943
<b>LDA</b>	21196.383	21351.466	23843.66	24147.583	24465.038	24796.191	25141.209	25500.263

LDA underestimates stability of atom, GGA is closer

# Small Molecules

## Binding Energy

	exp (ev)	LDA	GGA	HF
H <sub>2</sub>	-4.753	-4.913	-4.540	-3.64
LiH	-2.509	-2.648	-2.322	
O <sub>2</sub>	-5.230	-7.595	-6.237	-1.28
H <sub>2</sub> O	-10.078	-11.567	-10.165	
F <sub>2</sub>	-1.66	-3.32		1.37

Binding energy too high in LDA, GGA is closer but sometimes bound to weak. Pure Hartree Fock without corrections is terrible.

# Lattice Parameters in Solids

	exp	LDA	$\Delta$	GGA	$\Delta$
<b>Si</b>	5.427	5.4	-0.50%	5.49	1.16%
<b>Ge</b>	5.65	5.62	-0.53%	5.74	1.59%
<b>GaAs</b>	5.65	5.62	-0.53%	5.73	1.42%
<b>Al</b>	4.03	3.98	-1.31%	4.09	1.57%
<b>Cu</b>	3.60	3.52	-2.35%	3.62	0.44%
<b>Ag</b>	4.07	4.00	-1.69%	4.17	2.47%
<b>Ta</b>	3.30	3.26	-1.12%	3.32	0.80%
<b>W</b>	3.16	3.14	-0.67%	3.18	0.67%
<b>Pt</b>	3.91	3.90	-0.41%	3.97	1.49%
<b>Au</b>	4.06	4.05	-0.13%	4.16	2.48%

LDA tends to “overbind”, GGA “underbinds” GGA error more variable

# Bulk Modulus in Solids (in GPA)

	<b>exp</b>	<b>LDA</b>	$\Delta$	<b>GGA</b>	$\Delta$
<b>Si</b>	99	96	-3.03%	83	-16.16%
<b>Ge</b>	77	78	1.30%	61	-20.78%
<b>GaAs</b>	76	74	-2.63%	65	-14.47%
<b>Al</b>	77	84	9.09%	73	-5.19%
<b>Cu</b>	138	192	39.13%	151	9.42%
<b>Ag</b>	102	139	36.27%	85	-16.67%
<b>Ta</b>	193	224	16.06%	197	2.07%
<b>W</b>	310	337	8.71%	307	-0.97%
<b>Pt</b>	283	307	8.48%	246	-13.07%
<b>Au</b>	172	198	15.12%	142	-17.44%

LDA tends to be too stiff. GGA too soft

# Oxides

	<b>exp</b>	<b>LDA</b>	$\Delta$	<b>GGA</b>	$\Delta$
<b>MgO</b>	4.21	4.17	-0.95%		
<b>TiO<sub>2</sub> (a)</b>	4.59	4.548	-0.92%	4.623	0.72%
<b>TiO<sub>2</sub> (c)</b>	2.958	2.944	-0.47%	2.987	0.98%
<b>Al<sub>2</sub>O<sub>3</sub></b>	5.128	5.091	-0.72%	5.185	1.11%
<b>BaTiO<sub>3</sub></b>	4	3.94	-1.50%		
<b>PbTiO<sub>3</sub></b>	3.9	3.833	-1.72%	3.891	-0.23%
<b>SnO<sub>2</sub></b>	4.737	4.637	-2.11%		
<b><math>\beta</math>-MnO<sub>2</sub> (a)</b>	4.404	4.346	-1.32%	4.444	0.91%
<b>b-MnO<sub>2</sub> (c)</b>	2.876	2.81	-2.29%	2.891	0.52%

## Summary of Geometry Prediction

LDA under-predicts bond lengths (always ?)

GGA error is less systematic though over-prediction is common.

errors are in many cases < 1%, for transition metal oxides < 5%

# Predicting Structure: The Energy Scales

Accuracy required to predict physical behavior is astonishing

V      Atomic energy:            -1894.074 Ry

Fcc V            :            -1894.7325 Ry

Bcc V            :            -1894.7125 Ry

**Cohesive energy** is 0.638 Ry (0.03% of total E)

**Fcc/bcc difference** is 0.02 Ry (0.001% of total E)

**Mixing energies** are also order  $10^{-6}$  fraction of total E

How can we ever get physical behavior correct ?

**Large cancellation of errors !**

## Summary: Comparing Energy of Structures

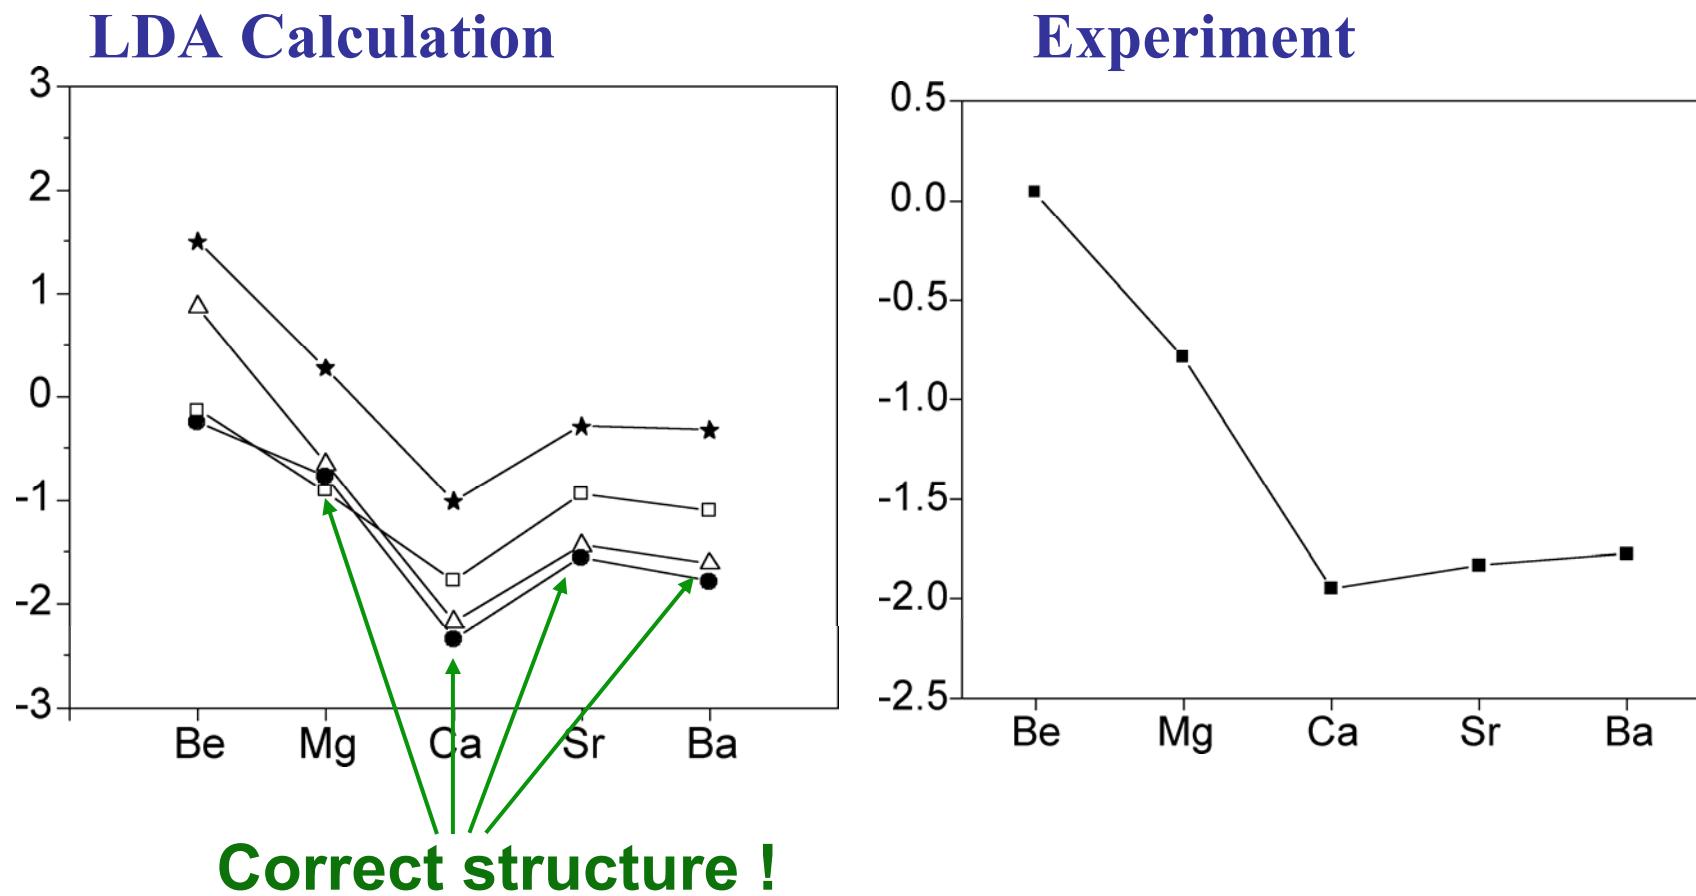

For most elements, both LDA and GGA predict the correct structure for a material (as far as we know)

Notable exceptions: Fe in LDA; materials with substantial electron correlation effects (e.g. Pu)

High Throughput studies are now possible.

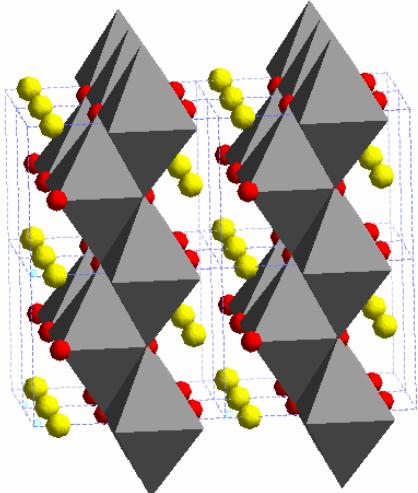

# Metal Hydrides

Hydride formation energy:  $M + H_2 \rightarrow MH_2$

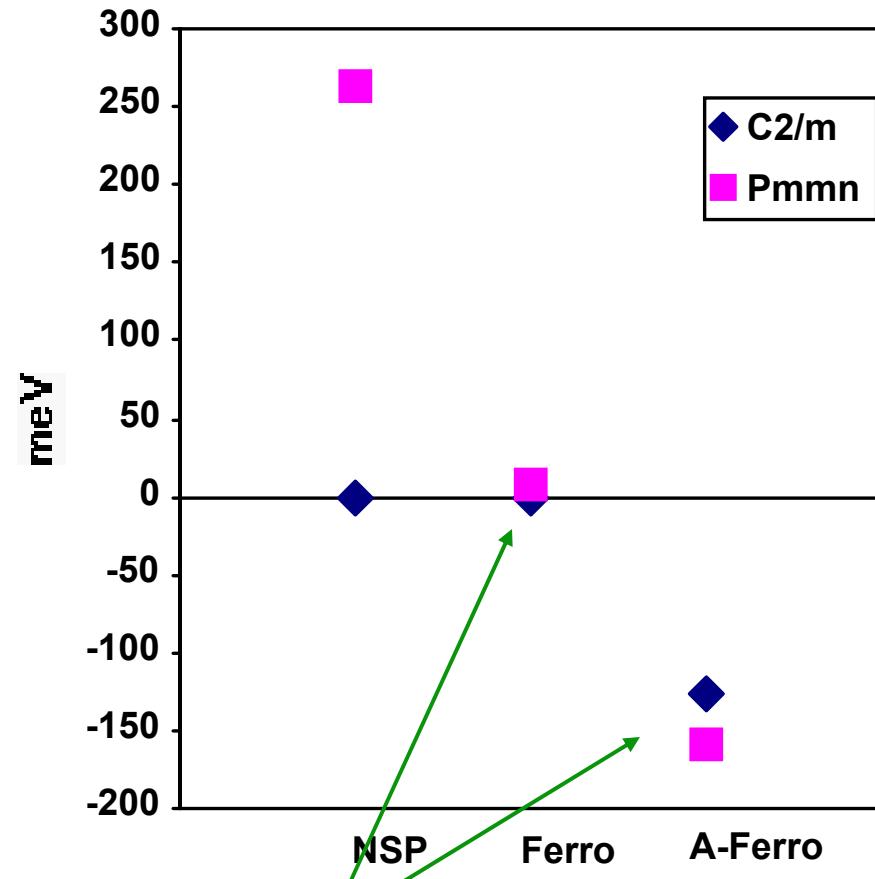

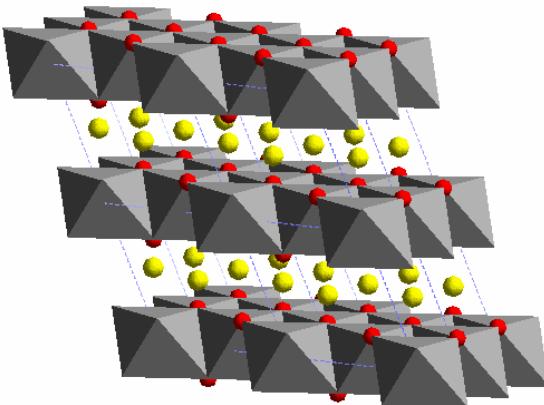

# Spin Polarization can be Important (in particular for transition metal compounds)

Pmmn: structure of  $\text{LiMnO}_2$

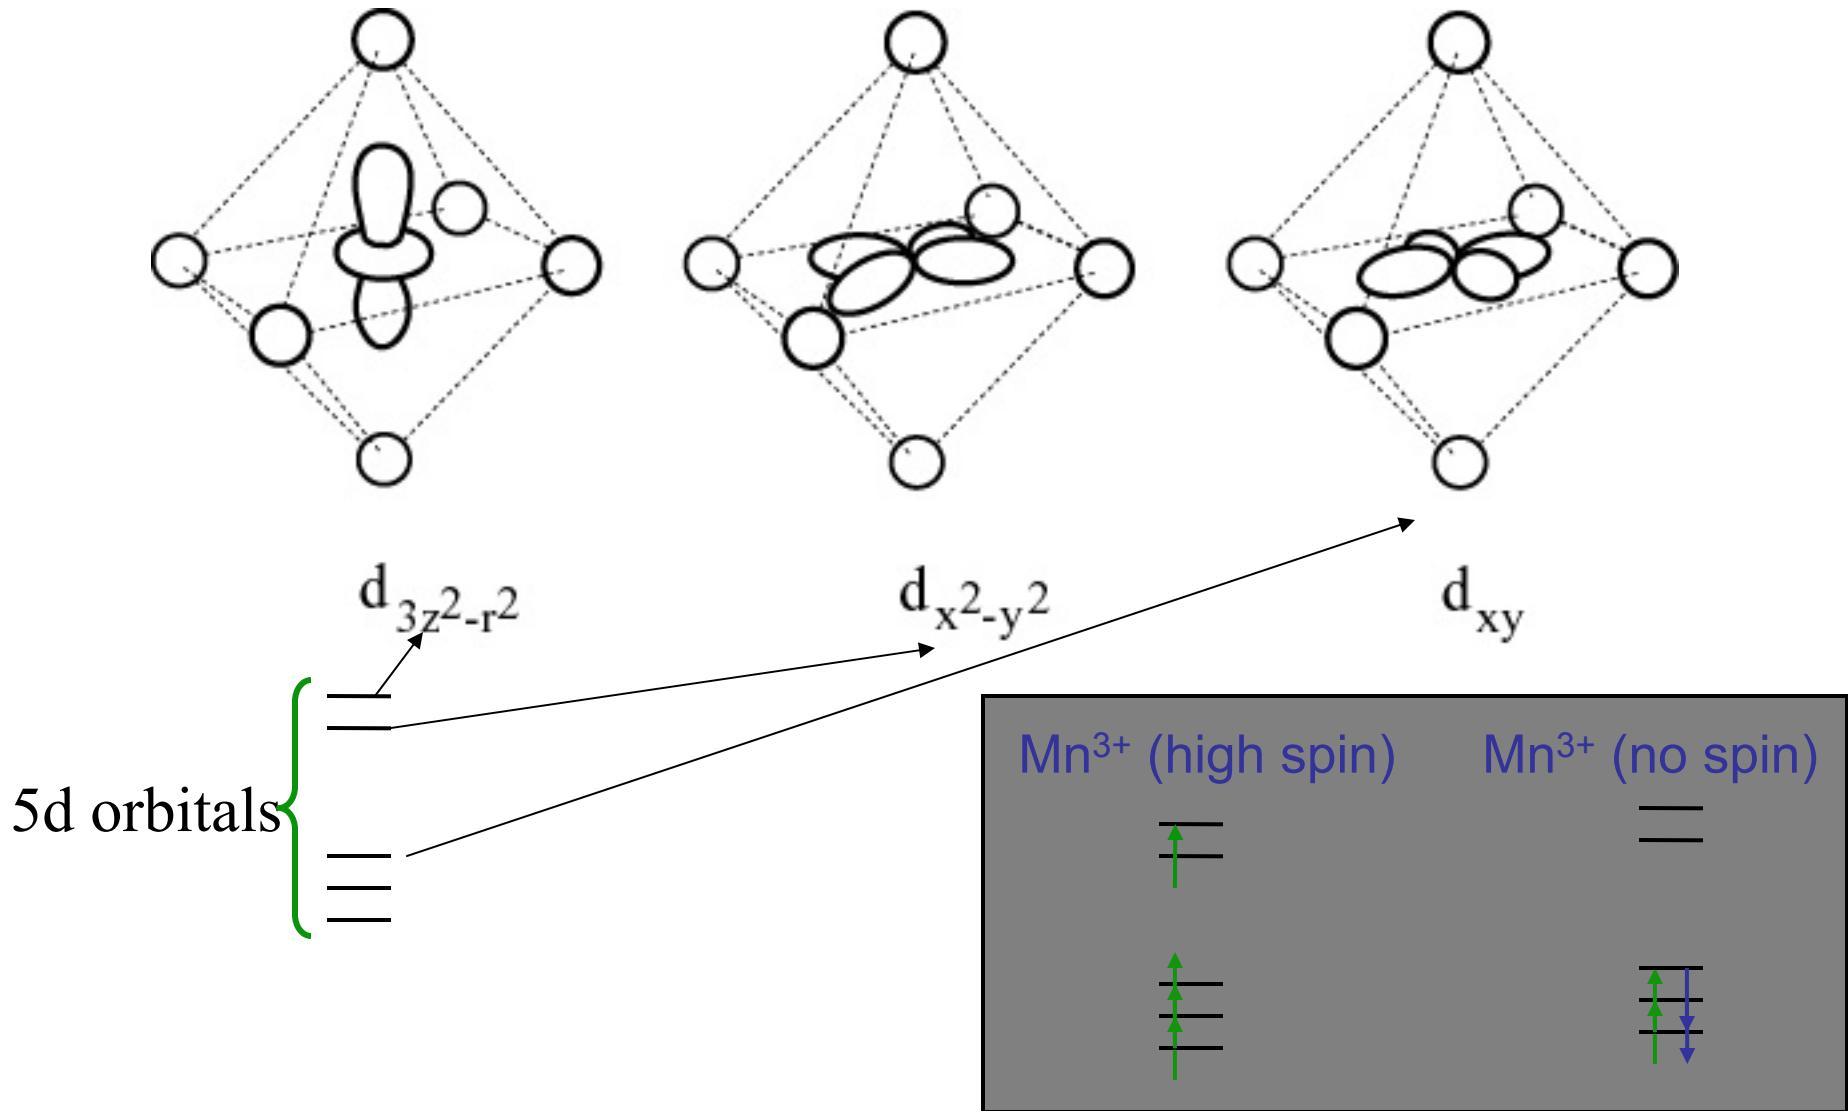

C2/m: other common structure

Spin polarized calculations

# Orbital filling depends on spin polarization

# Reaction Energies

Reaction	Exp (eV)	LDA (eV)	$\Delta$
Li (bcc) + Al (fcc) -> LiAl (compound)	-0.2457	-0.2234	9.08%
0.5 Cu(fcc) + 0.5 Au(fcc) -> CuAu	-0.053	-0.0193	63.58%
Li(bcc) + CoO <sub>2</sub> -> LiCoO <sub>2</sub>	-4.25	-3.75	11.76%

## Redox Reactions can be more Problematic

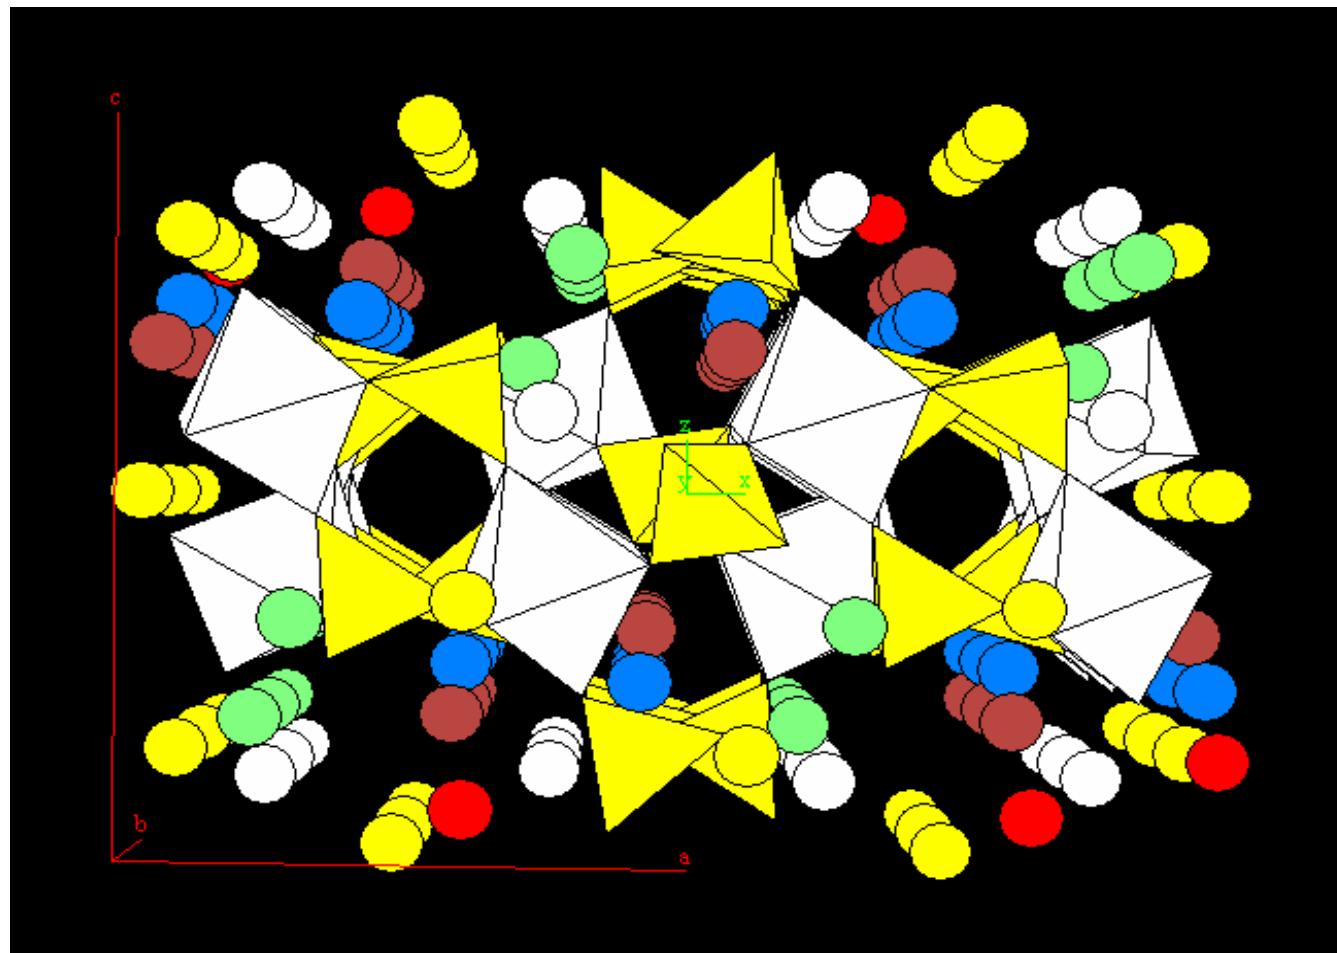

GGA	Exp
2.8 eV	3.5 eV
3.6 eV	4.1 eV
3.3 eV	4.6 eV

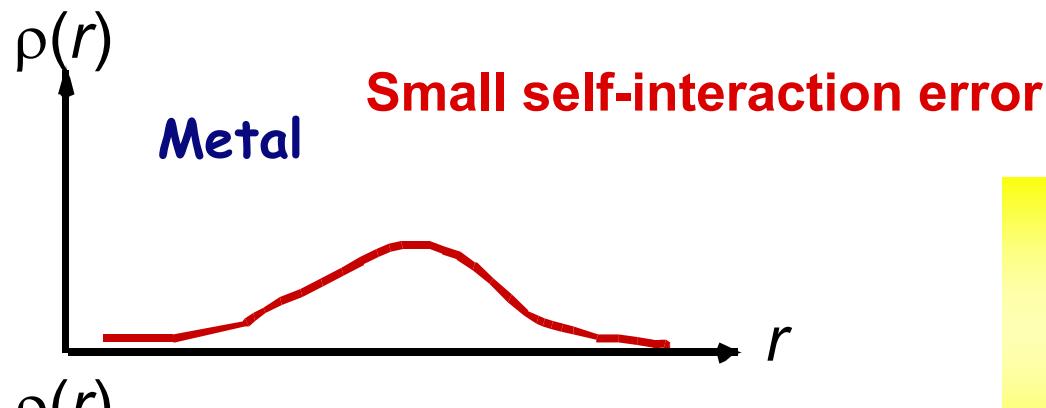

All these reactions involve the transfer of an electron from a delocalized state in Li metal to a localized state in the transition metal oxide (phosphate)

# Structure of $\text{LiV}_2(\text{PO}_4)_3$

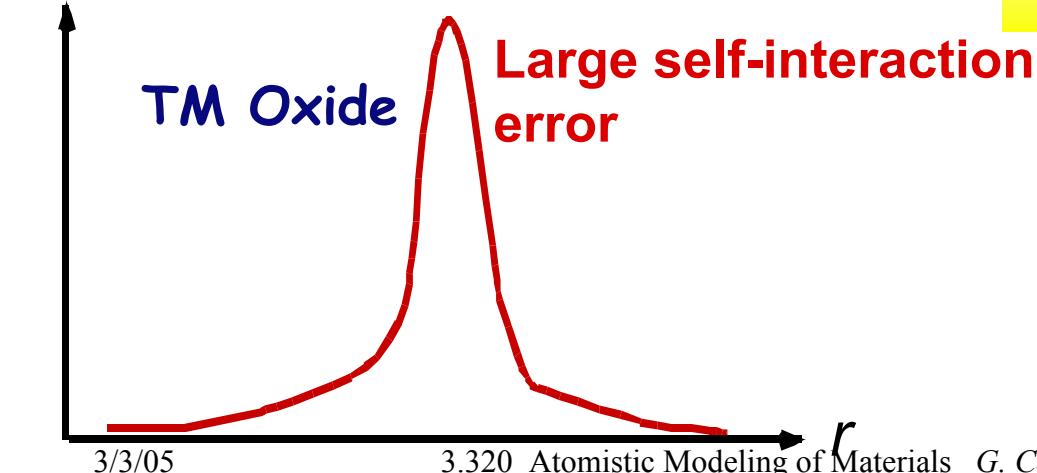

*In standard DFT an electron interacts with the effective potential generated by all the electrons (including itself)*

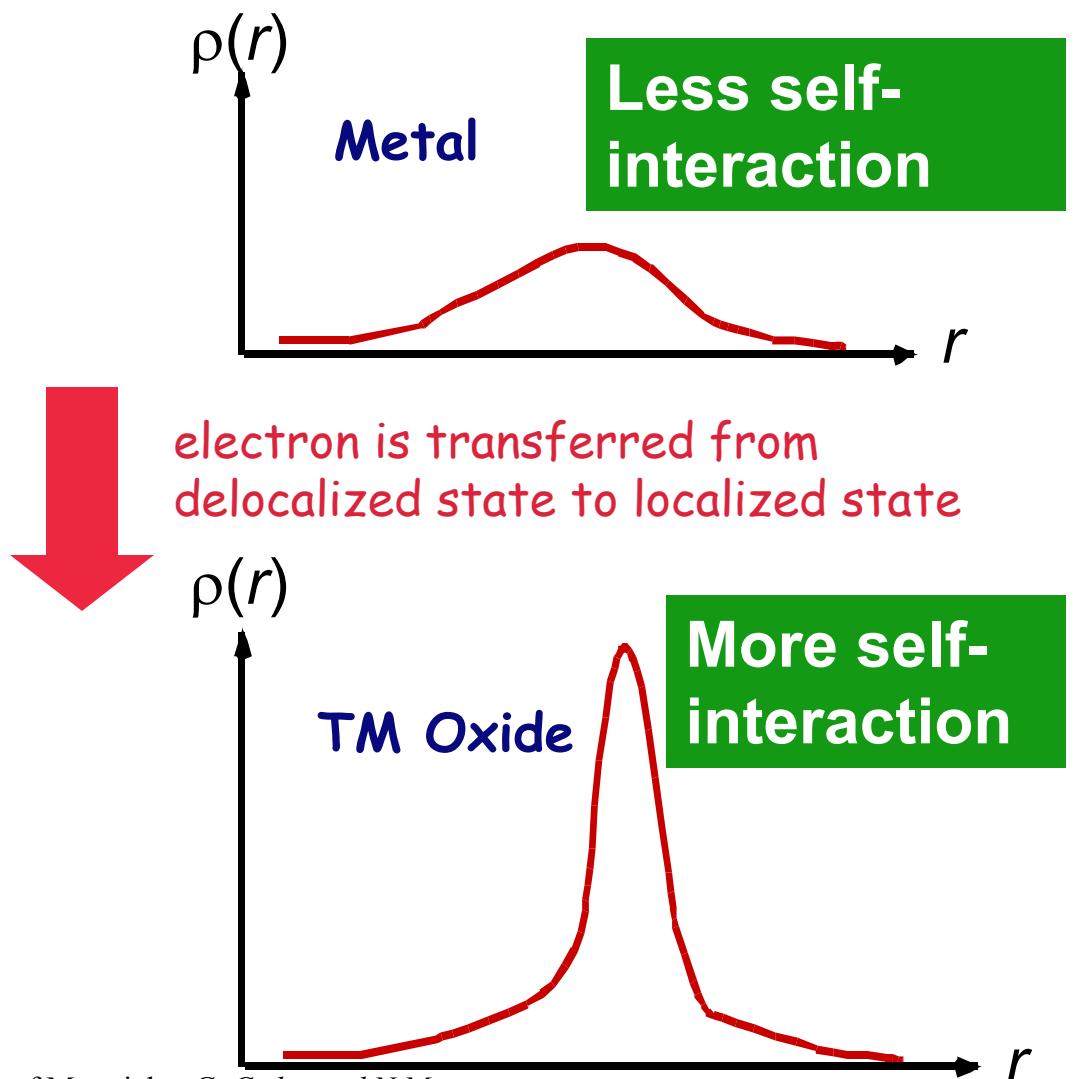

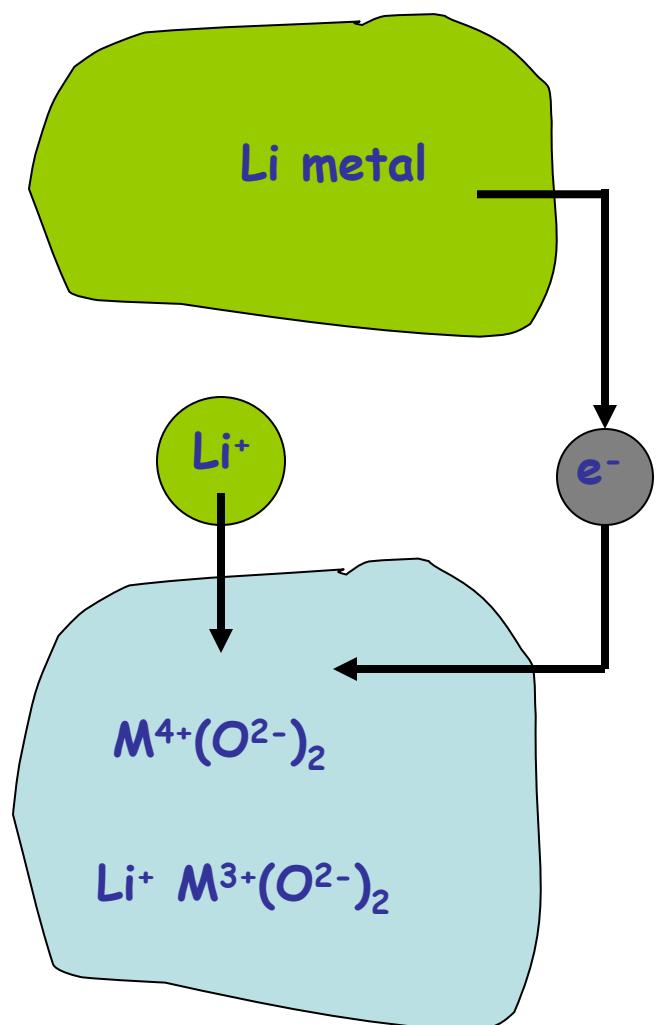

$$H = \sum_i H_i = \sum_{i=1}^{N_e} \nabla_i^2 + \sum_{i=1}^{N_e} V_{nuclear}(r_i) + \sum_{i=1}^{N_e} V_{effective}(r_i)$$

**Self interaction in DFT  
is key problem in transition  
metal oxides**

## Li insertion into cathode transfers electron from a delocalized to a localized state

## Summary (LDA)

Lattice constants: 1-3% too small

Cohesive Energies: 5-20% too strongly bound

Bulk Modulus: 5-20% (largest errors for late TM)

Bandgaps: too small

GGA gives better cohesive energies. Effect on lattice parameters is more random. GGA important for magnetic systems.
