## Kramers-Kronig relations

Relate  $\epsilon_1(\omega)$  and  $\epsilon_2(\omega)$  $\alpha \equiv$  absorption coefficient

$$\alpha = \frac{2\omega K}{c}$$

Reflectivity (normal incidence)

$$R = \frac{(n-1)^2 + K}{(n+1)^2 + K}$$

- in transparent range of  $\omega$ :

$$K \rightarrow 0; R \rightarrow \left(\frac{n-1}{n+1}\right)^2$$

Snell's Law

$$\frac{\sin\theta_1}{\sin\theta_2} = \frac{n_2}{n_1}$$

Total internal reflection

$$\theta_1 > \theta_{\text{ext}} = \sin^{-1}\left(\frac{n_2}{n_1}\right)$$

Reflection (materials  $n_1, n_2$ )

$$R = \left(\frac{n-1}{n+1}\right)^2 \quad \text{normal incidence}$$

Diamond:  $n \approx 2.4$ TiO<sub>2</sub>:  $n = 2.6$ ZrSiO<sub>4</sub>:  $n = 1.9$ 

Material	$\theta_c$	$n$	R
Water	48.6°	1.33	0.02
Glass	41.8°	1.50	0.04
Crystal glass	31.8°	1.90	0.10
diamond	24.4°	2.42	0.17

Index matching

$$n_{(\text{medium})} = n_{(\text{material})} \Rightarrow \text{no reflection}$$

Anti-reflection coating

$$R = \frac{n_2^2 - n_1 n_3}{n_2^2 + n_1 n_3} \quad \begin{array}{c} n_1 \text{ (air)} \\ \hline n_2 \text{ (coating)} \\ \hline n_3 \text{ (material)} \end{array} \quad \begin{array}{c} \downarrow \\ t \\ \uparrow \end{array}$$

$$= 0 \text{ when } n_2 = \sqrt{n_1 n_3}$$

**Example**

for solar cell:  $n_3$  (silicon)

$$n_2 t = \frac{\lambda}{4} \quad \text{quarter wave film}$$

for glass:

$$n_3 = 1.5; \text{ air : } n_1 = 1.0 \Rightarrow n_2 = 1.22$$

$$\text{MgF}_2 \quad n_2 = 1.384 \Rightarrow R = 0.12$$

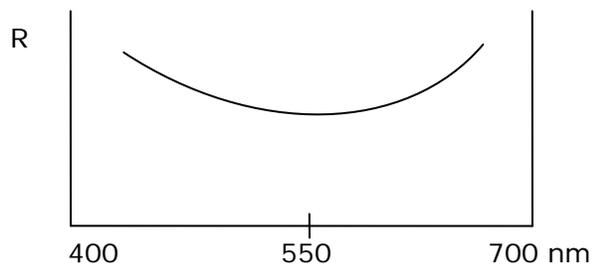

**Example**

AR coating for silicon

$$n_{\text{Si}} = 3.5 \Rightarrow n_{\text{AR}} = 1.87$$

$$n_{\text{SiO}_2} = 1.51$$

$$\lambda = 550 \text{ nm} \rightarrow t = 91 \text{ nm}$$

Electromagnetic optics**Electromagnetic Field**  $\vec{E}(\vec{r}, t)$ ,  $\vec{H}(\vec{r}, t)$ **Maxwell's Equations**

$$\vec{\nabla} \times \vec{H} = \epsilon_0 \frac{\partial \vec{E}}{\partial t} \quad \vec{\nabla} \times \vec{E} = -\mu_0 \frac{\partial \vec{H}}{\partial t}$$

$$\vec{\nabla} \cdot \vec{E} = 0 \quad \vec{\nabla} \cdot \vec{H} = 0$$

**Monochromatic EM Wave**

$$\vec{E}(\vec{r}, t) = \text{Re} \left\{ \vec{E}'(\vec{r}) \exp(j\omega t) \right\}$$

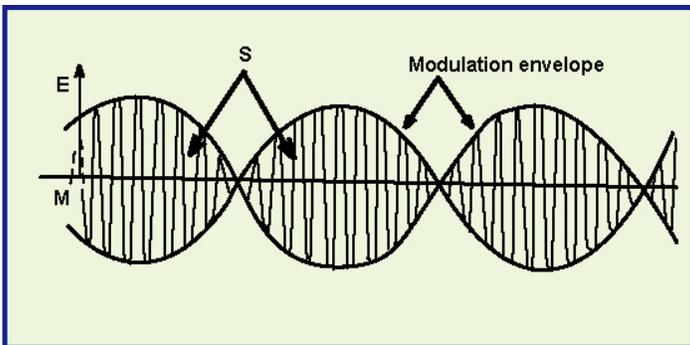

Each of the six scalar components of  $\vec{E}$  &  $\vec{H}$  must satisfy the Helmholtz Equation

$$\nabla^2 u + k^2 u = 0$$

wave vector:

$$k = \frac{\omega}{c} = \omega(\epsilon\mu_0)^{1/2} = nk_0 = \frac{n\omega}{c_0} = \frac{2\pi}{\lambda}$$

$$c = \frac{\omega}{k} : \text{phase velocity; velocity } v_g = \frac{d\omega}{dk} = \text{group}$$

The carrier propagates with the phase velocity  $c$ . The slowly varying envelop propagates at the group velocity,  $v_g$ .

**Transverse EM Plane Waves (TEM)**

- $\vec{E}(\vec{r}, t)$ ,  $\vec{H}(\vec{r}, t)$  are plane waves with wave vector  $\vec{k}$
- $\vec{E}$ ,  $\vec{H}$ ,  $\vec{k}$  are mutually orthogonal

$$\vec{E}(\vec{r}) = E_0 e^{j\vec{k}\vec{r}}, \quad \vec{H}(\vec{r}) = H_0 e^{j\vec{k}\vec{r}}$$

Phenomenology of PropertiesAbsorption

$$\chi = \chi' - i\chi''; \quad \varepsilon = \varepsilon_0 (1 + \chi)$$

$$\begin{aligned} k &= \omega(\varepsilon\mu_0)^{\frac{1}{2}} = (1 + \chi)^{\frac{1}{2}} k_0 = (1 + \chi' + i\chi'')^{\frac{1}{2}} k_0 \\ &= \beta - i\frac{1}{2}\alpha \end{aligned}$$

$$U(x) = Ae^{-ikx} = Ae^{\frac{-\alpha x}{2}} e^{-i\beta x}$$

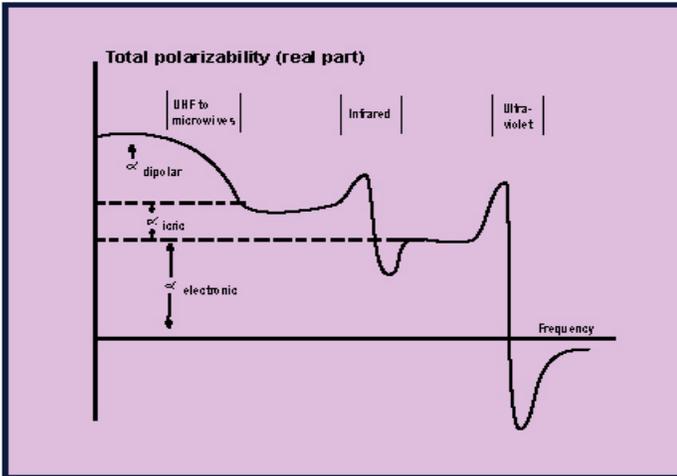

$$I(x) \propto |U(x)|^2 \propto e^{-\alpha x}$$

Resonant atoms in host medium

$$n(\nu) \approx n_0 + \frac{\chi'(\nu)}{2n_0}, \quad \alpha(\nu) \approx -\left(\frac{2\pi\nu}{n_0}\right)\chi''(\nu)$$

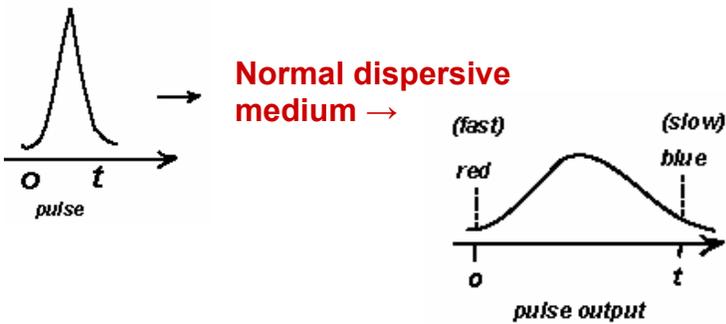

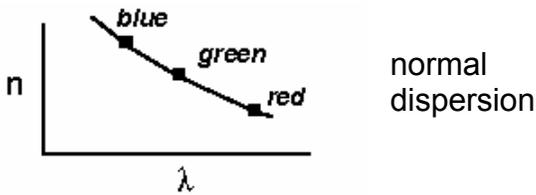

Fiber materials for transmission

- Electronic polarizability not important for IR fibers
- Heavy atom  $\rightarrow$  weaker bond  
 $\rightarrow$  long  $\lambda_0$

Frequency dependence of the several contributions to polarizability.

Dispersion  $\equiv \frac{dn}{d\lambda}$

**group index**  $n_g = n - \lambda_0 \frac{dn}{d\lambda_0}$

**group velocity**

$$v_g = \frac{c_0}{n_g} = c_0 \left( n - \lambda_0 \frac{dn}{d\lambda_0} \right)^{-1}$$

**Dispersion coefficient**

$$D_\lambda = \frac{d}{d\lambda} \left( \frac{1}{v_g} \right) = -\frac{\lambda_0}{c_0} \frac{d^2 n}{d\lambda_0^2}$$

$$D_\lambda = \frac{\text{temporal spread}}{\text{length} \cdot \text{spectral width}} = \frac{\text{ps}}{\text{km} \cdot \text{nm}}$$

$$|D_\lambda| \sigma_\lambda = \frac{\text{seconds of pulse broadening}}{\text{distance travel}}$$

$\sigma_\lambda$  : spectral width

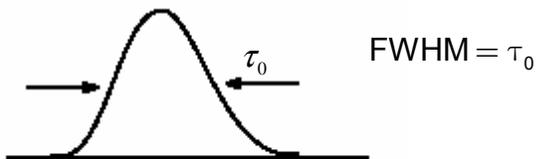

pulse delay:  $\tau_d = \frac{z}{v}$

pulse spreading:  $D_\nu = \frac{d}{d\nu} \left( \frac{1}{v_g} \right)$

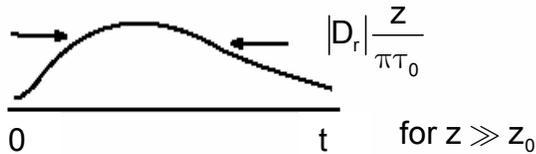

$$\sigma_\tau = |D_\nu| \sigma_\nu z \quad \text{temporal width}$$

Gaussian pulse

$$A(0,t) = \exp \left( -\frac{t^2}{\tau_0^2} \right)$$

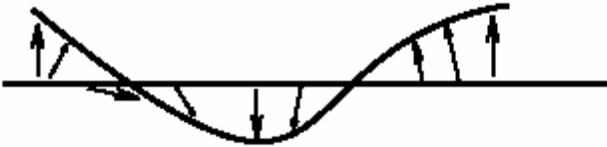

$$\tau_2 = \tau_0 \left[ 1 + \left( \frac{z}{z_0} \right)^2 \right]^{\frac{1}{2}}$$

## Polarization

The time course of direction of  $\vec{E}(\vec{r}, t)$

Helical rotation of circular polarization

### 1. Plane Polarization

$\vec{E}$  at fixed direction of  $\vec{k}$

$$\vec{E}(z, t) = a_y \vec{y} e^{i(kz - \omega t)}; \quad \omega = kc$$

monochromatic light

$$\vec{E}(\vec{r}, t) = \text{Re} \left\{ \vec{A} \exp \left[ i 2\pi \left( t - \frac{z}{c} \right) \right] \right\}$$

$\nu$  = frequency of photons

$z$  = direction of propagation

$c$  = phase velocity

Amplitude has  $\vec{x}$  and  $\vec{y}$  component:

$$\vec{A} = A_x \vec{x} + A_y \vec{y}$$

$$\vec{E}(z,t) = E_x \vec{x} + E_y \vec{y}$$

$$\downarrow$$

$$a_x \cos \left[ 2\pi \nu \left( t - \frac{z}{c} \right) + \phi_x \right]$$

$\Rightarrow$  at fixed  $z$ ,  $\vec{E}$  rotates periodically in  $x$ - $y$  plane

2. General Solution: elliptical polarization

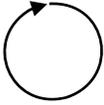

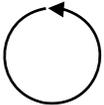

$$\frac{E_x^2}{a_x^2} + \frac{E_y^2}{a_y^2} - 2 \cos \phi \frac{E_x E_y}{a_x a_y} = \sin^2 \phi$$

### Matrix Representation

Matrix representation is a simplified way to perform first order calculations where small angles can be assumed. It can be used for order of magnitude calculations to obtain general values for a broad range of optical devices.

$$E = \begin{pmatrix} E_x \\ E_y \\ E_z \end{pmatrix} \quad \begin{aligned} A_x &= a_x e^{i\phi x} \\ A_y &= a_y e^{i\phi y} \end{aligned}$$

“Jones” vector:  $\vec{J} = \begin{bmatrix} A_x \\ A_y \end{bmatrix} = \text{operator on } \vec{E}$

$\begin{bmatrix} 1 \\ 0 \end{bmatrix}$	linear polarized in $\vec{x}$	$\longleftrightarrow$
$\begin{bmatrix} \cos \theta \\ \sin \theta \end{bmatrix}$	linear polarized at $\theta$ to $\vec{x}$	$\nearrow$
$\frac{1}{\sqrt{2}} \begin{bmatrix} 1 \\ i \end{bmatrix}$	right circular	
$\frac{1}{\sqrt{2}} \begin{bmatrix} 1 \\ -i \end{bmatrix}$	left circular	

Linear polarization  $\equiv \Sigma$  (right + left circular)

$$\begin{bmatrix} \cos \theta \\ \sin \theta \end{bmatrix} = \frac{1}{\sqrt{2}} e^{-i\theta} + \frac{1}{\sqrt{2}} e^{i\theta}$$

### Jones Transformation Matrix

$$\vec{J}_2 = \vec{T}_1^{-1}$$

$$\begin{pmatrix} A_{2x} \\ A_{2y} \end{pmatrix} = \begin{pmatrix} T_{11} & T_{12} \\ T_{21} & T_{22} \end{pmatrix} \begin{pmatrix} A_{1x} \\ A_{1y} \end{pmatrix}$$

### Linear Polarizer

$$T = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \text{ (polarizes wave in x-direction)}$$

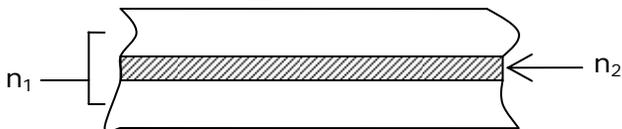

$$A_{1x}, A_{1y} \rightarrow A_{1x}, 0$$

$$\vec{E}_{\text{out}} = \vec{T}_{\text{in}}$$

### Guided Wave Optics – Introduction

- Free space
- Guided by confinement in high refractive index medium

### Optical wave guide $n_2 > n_1$

Planar Mirrors

TEM plane waves

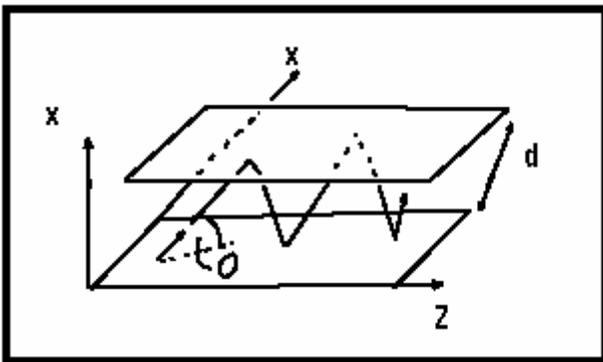

$$\lambda = \frac{\lambda_0}{n}$$

$$k = nk_0$$

$$k = nk_0$$

$$c = \frac{c_0}{n}$$

polarized in x-direction

 $\vec{k}$  in y-z plane at  $\theta$  to z-axis

1.  $\vec{E} \parallel$  mirror plane
2. each reflection  $\rightarrow \Delta\phi = \pi$  with  $\vec{A}, |\vec{k}|$  unchanged
3. self-consistency: after two reflections, wave reproduces itself  $\equiv$  eigenmode of wave

$\Rightarrow$  "bounce angles"  $\theta$  are discrete (quantized)

$$m\lambda = 2d \sin \theta_m$$

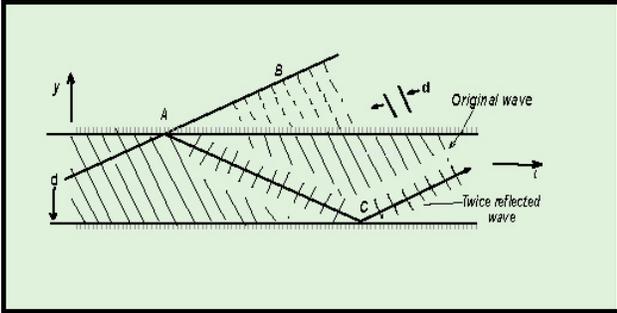

$$\vec{E}_m(y, z) = U_m(y) \exp(-i\beta_m z)$$

$\beta = k_z = k \cos \theta$  propagation constant

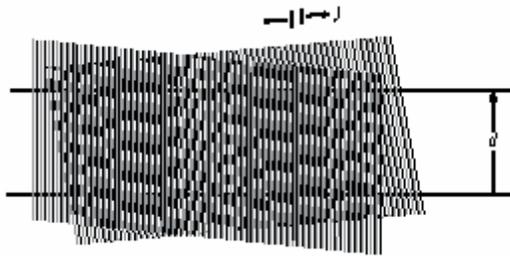

$$= \beta_m \text{ (quantized)}$$

$$= k \cos \theta_m$$

$U_m(y) =$  transverse distribution

(a) Condition of self-consistency: as a wave reflects twice it duplicates itself

(b) At angles for which self-consistency is satisfied, the two waves interfere and create a wave that does not change with  $t$ .

Optical power  $\propto |E|^2 \propto a_m^2$

Number of Modes  $M$

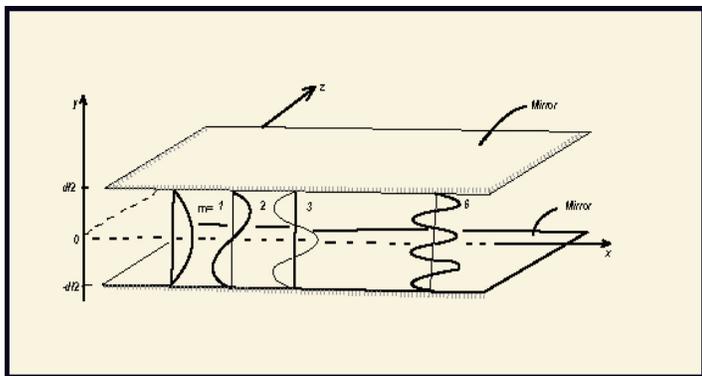

$$M \geq \frac{2d}{\lambda}$$

$M \uparrow$  with  $d$

$\lambda_{\max} = 2d$  : cut off  $\lambda$

$\nu_{\min} = \frac{c}{2d}$  : cut off  $\nu$

$d \leq \lambda \leq 2d$  single mode

Field distributions of the modes of a planar-mirror waveguide

### Group velocity of pulse

$$v_g = \frac{d\omega}{d\beta}$$

$$\beta_m^2 = \left(\frac{\omega}{c}\right)^2 - \frac{m^2\pi^2}{d^2} \quad \text{dispersion relation}$$

$$\begin{aligned} v_{\text{mode}} &= \frac{d\omega}{d\beta_m} = c^2 \frac{\beta_m}{\omega} \\ &= c^2 \frac{k \cos \theta_m}{\omega} = c \cdot \cos \theta_m \end{aligned}$$

- longer zigzag path  $\rightarrow$  slower group velocity
- different modes  $\rightarrow$  different  $v_g \rightarrow$  different transverse  $u(y)$  as wave propagates.
