### 5.62 Lecture \#16: Chemical Equilibrium. I.

Readings: Hill, pp. 177-182
Maczek, pp. 77-83
Metiu, pp. 179-191
Following the treatment of equilibrium in 5.60.

$$
\begin{array}{ll}
\mathrm{aA}+\mathrm{bB}=\mathrm{cC}+\mathrm{dD} & \mathrm{~A}, \mathrm{~B}, \mathrm{C}, \mathrm{D} \text { are all ideal gases } \\
\mu_{\mathrm{i}}\left(\mathrm{~T}, \mathrm{p}_{\mathrm{i}}\right)=\mu_{\mathrm{i}}^{\mathrm{o}}(\mathrm{~T})+\mathrm{RT} \ln \mathrm{p}_{\mathrm{i}} &
\end{array}
$$

${ }^{\circ}$ means standard state, usually $\mathrm{p}^{\circ}=1$ bar.
at equilibrium,

$$
\mathrm{c} \mu_{\mathrm{C}}+\mathrm{d} \mu_{\mathrm{D}}-\mathrm{a} \mu_{\mathrm{A}}-\mathrm{b} \mu_{\mathrm{B}}=0
$$

plug in equations for each $\mu_{\mathrm{i}}\left(\mathrm{T}, \mathrm{p}_{\mathrm{i}}\right)$

$$
0=\left[\mathrm{c} \mu_{\mathrm{C}}^{\mathrm{o}}(\mathrm{~T})+\mathrm{d} \mu_{\mathrm{D}}^{\mathrm{o}}(\mathrm{~T})-\mathrm{a} \mu_{\mathrm{A}}^{\mathrm{o}}(\mathrm{~T})-\mathrm{b} \mu_{\mathrm{B}}^{\mathrm{o}}(\mathrm{~T})\right]+\mathrm{R} \operatorname{Tn} \frac{\mathrm{p}_{\mathrm{C}}^{\mathrm{c}} \mathrm{p}_{\mathrm{D}}^{\mathrm{d}}}{\mathrm{p}_{\mathrm{A}}^{\mathrm{a}} \mathrm{p}_{\mathrm{B}}^{\mathrm{b}}}
$$

term in [ ] is $\Delta \mathrm{G}^{\circ}(\mathrm{T})$.
In 5.60 we can look up values for $\Delta \mathrm{G}_{\mathrm{f}}^{\mathrm{o}}(\mathrm{T})$ for each substance. In 5.62 we will use Statistical Mechanics to compute each $\mu_{\mathrm{i}}^{\circ}(\mathrm{T})$.

$$
\begin{aligned}
& 0=\Delta \mathrm{G}^{\circ}(\mathrm{T})+\mathrm{RT} \ln \mathrm{~K}_{\mathrm{p}}(\mathrm{~T}) \\
& \mathrm{K}_{\mathrm{p}}(\mathrm{~T})=\mathrm{e}^{-\Delta \mathrm{G}^{\circ}(\mathrm{T}) / \mathrm{RT}}
\end{aligned}
$$

$\mu_{\mathrm{i}}^{\mathrm{o}}(\mathrm{T})$ is chemical potential in units of $\mathrm{J} /$ mole of $\mathrm{i} . \mathrm{N}=\mathrm{N}_{\mathrm{a}}$. What is $\mu_{\mathrm{i}}$ ?

$$
\left(\frac{\partial \mathrm{G}}{\partial \mathrm{n}_{\mathrm{i}}}\right)_{\mathrm{T}, \mathrm{p}, \mathrm{n}_{\mathrm{j} \neq \mathrm{i}}}=\underbrace{\left(\frac{\partial \mathrm{A}}{\partial \mathrm{n}_{\mathrm{i}}}\right)_{\mathrm{T}, \mathrm{~V}, \mathrm{n}_{\mathrm{j} \neq \mathrm{i}}}}_{\substack{\text { more convenient in } \\ \text { Statistical Mechanics }}}
$$

Both definitions of $\mu$ will give the same result. You should verify this.

Need $\mu_{\mathrm{i}}^{\circ}(\mathrm{T})$ for $\mathrm{i}=\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}$

$$
\begin{aligned}
& A=-k T \ln Q \\
& \mu_{\mathrm{i}}=\left(\frac{\partial \mathrm{A}}{\partial \mathrm{n}_{\mathrm{i}}}\right)_{\mathrm{T}, \mathrm{~V}, \mathrm{n}_{\mathrm{j} j \mathrm{i}}}=-\mathrm{kT}\left(\frac{\partial \ln \mathrm{Q}}{\partial \mathrm{n}_{\mathrm{i}}}\right)_{\mathrm{T}, \mathrm{~V}} \\
& \mathrm{Q}_{\mathrm{i}}=\left(\mathrm{q}_{\text {trans }, \mathrm{i}}^{\mathrm{N}_{\mathrm{i}}} / \mathrm{N}_{\mathrm{i}}!\right) \mathrm{q}_{\text {int }, \mathrm{i}}^{\mathrm{N}} \\
& \ln \mathrm{Q}_{\mathrm{i}}=\mathrm{N}_{\mathrm{i}} \ln \mathrm{q}_{\text {trans }, \mathrm{i}}-\mathrm{N}_{\mathrm{i}} \ln \mathrm{~N}_{\mathrm{i}}+\mathrm{N}_{\mathrm{i}}+\mathrm{N}_{\mathrm{i}} \ln \mathrm{q}_{\mathrm{int}, \mathrm{i}} \\
& \frac{\partial \ln \mathrm{Q}_{\mathrm{i}}}{\partial \mathrm{n}_{\mathrm{i}}}=\frac{\partial \ln \mathrm{Q}}{\partial \mathrm{~N}_{\mathrm{i}}} \frac{\partial \mathrm{~N}_{\mathrm{i}}}{\frac{\mathrm{~N}_{\mathrm{i}}}{\partial \mathrm{~N}_{\mathrm{i}}}}=\mathrm{N}_{\mathrm{a}}\left[\ln \mathrm{q}_{\text {trans, } \mathrm{i}}-\ln \mathrm{N}_{\mathrm{i}}-1+1+\ln \mathrm{q}_{\mathrm{int,}, \mathrm{i}}\right] \\
& =N_{a}\left[\ln \left(q_{\text {trans }, \mathrm{i}} / \mathrm{N}_{\mathrm{i}}\right)+\ln \left(\mathrm{q}_{\text {int }}^{*} \mathrm{e}^{-\theta_{\text {vib }, \mathrm{i}} / 2 \mathrm{~T}}\right)\right] \\
& \mu_{\mathrm{i}}^{\mathrm{o}}=-\mathrm{kTN}_{\mathrm{a}}\left[\ln \left(\mathrm{q}_{\text {trans, } \mathrm{i}} / \mathrm{N}_{\mathrm{a}}\right)+\ln \mathrm{q}_{\mathrm{int}, \mathrm{i}}^{*}-\frac{\theta_{\text {vib }, \mathrm{i}}}{2 \mathrm{~T}}\right]
\end{aligned}
$$

Look at the last term in the previous equation:

$$
\begin{aligned}
& \left(-\mathrm{kTN}_{\mathrm{a}}\right)\left(-\frac{\theta_{\text {vib, } \mathrm{i}}}{2 \mathrm{~T}}\right)=+\mathrm{kN} \mathrm{~N}_{\mathrm{a}} \frac{\mathrm{hc} \omega_{\mathrm{i}}}{2 \mathrm{k}}=+\mathrm{N}_{\mathrm{a}} \frac{\mathrm{hc} \omega_{\mathrm{i}}}{2}=\mathrm{E}_{0, \mathrm{i}} \\
& \mathrm{kTN}_{\mathrm{a}}=\mathrm{RT} \\
& \mu_{\mathrm{i}}^{\mathrm{o}}(\mathrm{~T})=-\mathrm{RT} \ln \left(\mathrm{q}_{\mathrm{i}}^{*} / \mathrm{N}_{\mathrm{a}}\right)+\mathrm{E}_{0, \mathrm{i}}
\end{aligned}
$$

We will soon need to worry about putting all chemical species into a common energy scale. This will be to set the zero of energy at all separated gas phase atoms.

Putting everything together to get $\Delta \mathrm{G}^{\circ}(\mathrm{T})$ :

$$
\Delta \mathrm{G}^{\circ}(\mathrm{T})=\left[\mathrm{cE}_{0, \mathrm{C}}+\mathrm{dE}_{0, \mathrm{D}}-\mathrm{aE}_{0, \mathrm{~A}}-\mathrm{bE} \mathrm{E}_{0, \mathrm{~B}}\right]-\mathrm{RT} \ln \left\{\frac{\left(\mathrm{q}_{\mathrm{C}}^{*} / \mathrm{N}_{\mathrm{a}}\right)^{\mathrm{c}}\left(\mathrm{q}_{\mathrm{D}}^{*} / \mathrm{N}_{\mathrm{a}}\right)^{\mathrm{d}}}{\left(\mathrm{q}_{\mathrm{A}}^{*} / \mathrm{N}_{\mathrm{a}}\right)^{\mathrm{a}}\left(\mathrm{q}_{\mathrm{B}}^{*} / \mathrm{N}_{\mathrm{a}}\right)^{\mathrm{b}}}\right\}
$$

The $E_{0, i}$ in the above equation should be reinterpreted as the energy of $v=0$ of species $i$ on an energy scale shared by all of the chemical species. This is the scale where the zero of energy is set at the energy of all separated gas phase atoms.

When we do all of the bookkeeping carefully, we have

$$
\begin{aligned}
\mathrm{K}_{\mathrm{p}}(\mathrm{~T}) & =\mathrm{e}^{+\mathrm{D}_{0}^{0} / \mathrm{RT}}\left[\frac{\left(\mathrm{q}_{\mathrm{C}}^{*} / \mathrm{N}_{\mathrm{a}}\right)^{\mathrm{c}}\left(\mathrm{q}_{\mathrm{D}}^{*} / \mathrm{N}_{\mathrm{a}}\right)^{\mathrm{d}}}{\left(\mathrm{q}_{\mathrm{A}}^{*} / \mathrm{N}_{\mathrm{a}}\right)^{\mathrm{a}}\left(\mathrm{q}_{\mathrm{B}}^{*} / \mathrm{N}_{\mathrm{a}}\right)^{\mathrm{b}}}\right] \\
\Delta \mathrm{D}_{0}^{0} & =\mathrm{cD}_{0, \mathrm{C}}+\mathrm{dD}_{0, \mathrm{D}}-\mathrm{aD}_{0, \mathrm{~A}}-\mathrm{bD}_{0, \mathrm{~B}}
\end{aligned}
$$

$D_{0, i}$ is the energy required to go from the $\mathrm{v}=0$ level of species i to all separated atoms.
If $\Delta D_{0}^{0}>0$, it means that the products have a larger total bonding energy than the reactants.

Here ${ }^{\circ}$ means at 0 K .

If $\Delta D_{0}^{0}>0$ the products are more stable than reactants and the $\mathrm{e}^{+\Delta \mathrm{D}_{0}^{0} / \mathrm{RT}}$ factor makes $\mathrm{K}_{\mathrm{p}}(\mathrm{T})$ large.

We need to put all of the zero point energies of the various products and reactants onto a common energy scale. This will be made clear by the following energy level diagram.

As drawn here, $\Delta \mathrm{D}_{0}=\mathrm{D}_{0, \mathrm{P}}-\mathrm{D}_{0, \mathrm{R}}>0$
But convention is to use dissociation energies, $\mathrm{D}_{0}$, where $\mathrm{D}_{0}$ is energy required to dissociate a molecule into atoms, where the "zero" of energy is set at the energy of all atoms separated. $-\varepsilon_{0}$ is the energy of the minimum of the potential curve (surface) below its separated atom asymptote.

Zero of $\overline{\mathrm{E}}$ is defined here to be at separated atoms because the same set of separated atoms is common to both $\sum$ (reactants) and $\sum$ (products). We put products and reactants onto a common $\overline{\mathrm{E}}$ scale.

The minimum of each potential energy curve (or surface) is at $-\varepsilon_{0}$. Thus the zero-point $(\mathrm{v}=0)$ level is at $-\varepsilon_{0}+\mathrm{E}_{0}$ (the 0 refers to the lowest electronic state). We use zero-point energies for each molecule so that we can use $\mathrm{q}_{\mathrm{vib}}^{*}$ rather than $\mathrm{q}_{\mathrm{vib}}$ for each molecule.

The dissociation energy, $D_{0}$, is the energy that must be added to the system to convert the molecule in its zero-point level into separated atoms ( $\mathrm{D}_{0}>0$ ).

$$
-\mathrm{D}_{0}=-\varepsilon_{0}+\mathrm{E}_{0} \quad \text { (The energy of the molecule in its zero-point level relative }
$$ to the zero-of-energy defined at separated atoms)

For several reactants, use shorthand (r and pare stoichiometric coefficients)

$$
\sum_{\text {reactants }} \mathrm{r}\left(-\varepsilon_{0, \mathrm{R}}+\mathrm{E}_{0, \mathrm{R}}\right)=\sum_{\text {reactants }} \mathrm{r}\left(-\mathrm{D}_{0, \mathrm{R}}\right)
$$

and for products

$$
\sum_{\text {products }} \mathrm{p}\left(-\varepsilon_{0, \mathrm{P}}+\mathrm{E}_{0, \mathrm{P}}\right)=\sum_{\text {products }} \mathrm{p}\left(-\mathrm{D}_{0, \mathrm{P}}\right)
$$

Thus the energy difference between products and reactants in their zero-pont levels is

$$
\begin{aligned}
& \sum_{\text {products }} \mathrm{p}\left(-\varepsilon_{0, \mathrm{P}}+\mathrm{E}_{0, \mathrm{P}}\right)-\sum_{\text {reactants }} \mathrm{r}\left(-\varepsilon_{0, \mathrm{R}}+\mathrm{E}_{0, \mathrm{R}}\right) \\
& \sum_{\text {products }} \mathrm{p}\left(-\mathrm{D}_{0, \mathrm{P}}\right)-\sum_{\text {reactants }} \mathrm{r}\left(-\mathrm{D}_{0, \mathrm{R}}\right)=-\Delta \mathrm{D}_{0}
\end{aligned}
$$

If $\Delta \mathrm{D}_{0}>0$, then \{products\} are more stable than $\{$ reactants \}, as shown on the figure above. BE REALLY CAREFUL ABOUT THIS!

$$
-\Delta \mathrm{D}_{0}=\mathrm{c} \overline{\mathrm{E}}_{0, \mathrm{C}}+\mathrm{d} \overline{\mathrm{E}}_{0, \mathrm{D}}-\mathrm{a} \overline{\mathrm{E}}_{0, \mathrm{~A}}-\mathrm{b} \overline{\mathrm{E}}_{0, \mathrm{~B}}
$$

Thus

$$
\Delta G^{0}=-\Delta D_{0}^{0}-R T \ln \left[\frac{\left(\mathrm{q}_{\mathrm{C}}^{*} / \mathrm{N}\right)^{\mathrm{c}}\left(\mathrm{q}_{\mathrm{D}}^{*} / \mathrm{N}\right)^{\mathrm{d}}}{\left(\mathrm{q}_{\mathrm{A}}^{*} / \mathrm{N}\right)^{\mathrm{a}}\left(\mathrm{q}_{\mathrm{B}}^{*} / \mathrm{N}\right)^{\mathrm{b}}}\right]=-\mathrm{RT} \ln \mathrm{~K}_{\mathrm{p}}
$$

( $\Delta \mathrm{D}_{0}^{0}$ means difference in dissociation energies relative to zero point energies computed at zero Kelvin. This is usually a non-trivial quantity, thus it is essential to get its sign correct.) Divide above equation by -RT and exponentiate:

$$
\mathrm{K}_{\mathrm{p}}=\mathrm{e}^{+\Delta \mathrm{D}_{0}^{0} / R \mathrm{RT}}\left[\frac{\left(\mathrm{q}_{\mathrm{C}}^{*} / \mathrm{N}\right)^{\mathrm{c}}\left(\mathrm{q}_{\mathrm{D}}^{*} / \mathrm{N}\right)^{\mathrm{d}}}{\left(\mathrm{q}_{\mathrm{A}}^{*} / \mathrm{N}\right)^{\mathrm{a}}\left(\mathrm{q}_{\mathrm{B}}^{*} / \mathrm{N}\right)^{\mathrm{b}}}\right] \quad\left[\text { note }+\Delta \mathrm{D}_{0}^{0}!\right]
$$

where $\mathrm{q}^{*} / \mathrm{N}=\left(\mathrm{q}_{\text {trans }} / \mathrm{N}\right) \mathrm{q}_{\text {int }}^{*}$

$$
\frac{\mathrm{q}_{\text {trans }}}{\mathrm{N}}=\frac{(2 \pi \mathrm{mkT})^{3 / 2}}{\mathrm{~h}^{3}} \frac{\mathrm{~V}}{\mathrm{~N}}=\frac{(2 \pi \mathrm{mkT})^{3 / 2}}{\mathrm{~h}^{3}} \frac{\mathrm{kT}}{\mathrm{p}}=\frac{(2 \pi \mathrm{~m})^{3 / 2}}{\mathrm{~h}^{3}}(\mathrm{kT})^{5 / 2} \frac{1}{\mathrm{p}}
$$

For $p=p^{0}=1$ bar $=10^{5} \mathrm{~Pa}, \Delta \mathrm{G}^{0}($ and Kp$)$ will be in standard state. The partial pressures that appear in the equilibrium expression are in units of bar. Standard state (i.e., specification of pressure) only appears in q trans. Note also, p here is the standard pressure in SI units ( $10^{5} \mathrm{~Pa}$ ), not the partial pressure at equilibrium of a specific chemical species.

$$
\begin{aligned}
& \mathrm{q}_{\text {int }}^{*}=\sum_{\substack{\mathrm{i} \\
\text { species }}} \mathrm{q}_{\mathrm{elec}}^{(\mathrm{i})} \mathrm{q}_{\mathrm{vib}}^{*(\mathrm{i})} \mathrm{q}_{\mathrm{rot}}^{(\mathrm{i})} \\
& \mathrm{q}_{\mathrm{vib}}^{*}=1 \text { for atoms }
\end{aligned}
$$

For molecules,

$$
q_{\mathrm{vib}}^{*}=\prod_{\mathrm{j}=1}^{\mathrm{m}}\left(1-\mathrm{e}^{-\theta_{\mathrm{vib}} / \mathrm{T}}\right)^{-1} \quad \begin{aligned}
& \mathrm{m}=3 \mathrm{n}-5 \text { linear } \\
& \mathrm{m}=3 \mathrm{n}-6 \text { non linear }
\end{aligned}
$$

vibrational modes
$\mathrm{q}_{\mathrm{rot}}=1$ for atoms
For molecules,

$$
\begin{array}{cl}
\mathrm{q}_{\mathrm{rot}}=\mathrm{T} / \sigma \theta_{\mathrm{rot}} & \text { diatomics, linear polyatomics } \\
\mathrm{q}_{\mathrm{rot}}=\frac{\pi^{1 / 2}}{\sigma} \frac{\mathrm{~T}^{3 / 2}}{\theta_{\mathrm{a}}^{1 / 2} \theta_{\mathrm{b}}^{1 / 2} \theta_{\mathrm{c}}^{1 / 2}} & \begin{array}{l}
\text { non-linear polyatomics (one } \\
\text { factor of } \frac{\mathrm{T}^{1 / 2}}{\theta_{\mathrm{i}}^{1 / 2}} \text { for each principal } \\
\\
\end{array} \\
& \text { axis of rotation) }
\end{array}
$$

## EXAMPLES OF CHEMICAL EQUILIBRIA

1. isomerization
2. dissociation (next time)
3. isotope exchange (next time)

1 Isomerization of a non-linear molecule

$$
\begin{aligned}
& A \rightarrow B \quad \text { i.e., } \ldots \text { cis-A } \rightarrow \text { trans-B } \\
& K_{p}=\frac{\left(q_{B}^{*} / N\right)^{b}}{\left(q_{A}^{*} / N\right)^{a}} e^{+\Delta D_{0}^{0} / R T}=\frac{\left(q_{\text {trans }, B} / N\right) q_{i n t, B}^{*}}{\left(q_{\text {trans }, A} / N\right) q_{i n t, A}^{*}} e^{+\Delta D_{0}^{0} / R T}
\end{aligned}
$$

Since $\left(q_{\text {trans, } A} / N\right)=\left(q_{\text {trans,B }} / N\right)$ for two isomers of the same molecule (because they have same mass),

$$
K_{p}=\frac{q_{i n t, B}^{*}}{q_{i n t, A}^{*}} e^{+\Delta D_{0}^{0} / R T}=\frac{g_{0, \mathrm{~B}} q_{v i b, \mathrm{~B}}^{*} q_{\mathrm{rot}, \mathrm{~B}}}{g_{0, \mathrm{~A}} q_{\mathrm{vib}, \mathrm{~A}}^{*} \mathrm{q}_{\mathrm{rot}, \mathrm{~A}}} e^{+\Delta \mathrm{D}_{0}^{0} / \mathrm{RT}}
$$

Let's try to arrive at a "physical" understanding for what drives a reaction - i.e. what determines $\mathrm{K}_{\mathrm{p}}$.

- Suppose $\mathrm{q}_{\text {int, } \mathrm{A}}^{*} \approx \mathrm{q}_{\text {int,B }}^{*}$ but A has lower energy ground state (larger dissociation energy).

At low T, equilibrium will lie toward the lower energy molecule. That is, the reaction mixture is almost all A because $\mathrm{K}_{\mathrm{p}}<1$. As T increases, $\mathrm{K}_{\mathrm{p}} \rightarrow 1$ because $\mathrm{e}^{+\Delta \mathrm{D}_{0}^{0} / \mathrm{RT}} \rightarrow 1$. So, there will be equal amounts of A and B at $\mathrm{RT} \gg\left|\Delta \mathrm{D}_{0}^{0}\right|$.

- Suppose $\mathrm{q}_{\text {int }, \mathrm{B}}^{*}>\mathrm{q}_{\text {int, } \mathrm{A}}^{*} \quad\left(\right.$ and $\Delta \mathrm{D}_{0}^{0}<0$, as before)

At low $\mathrm{T}, \mathrm{e}^{+\Delta \mathrm{D}_{0}^{0} / \mathrm{RT}} \ll 1$ so $\mathrm{K}_{\mathrm{p}} \ll 1$. Equilibrium mixture consists of almost all A. As T increases $\mathrm{e}^{+\Delta \mathrm{D}_{0}^{0} / \mathrm{RT}} \rightarrow 1$ again, but now $\mathrm{K}_{\mathrm{p}}>1$ because
$q_{i n t, B}^{*}>q_{i n t, A}^{*}$. So, at equilibrium at high $T$, the reaction mixture is more $B$ than $A$.

Next time: dissociation, isotope exchange.
Keep in mind that $\mathrm{K}_{\mathrm{p}}$ involves an enormous number of microscopic quantities. But many cancel, either exactly or approximately. $\Delta D_{0}^{0}$ is almost always the most important factor in determining $K_{p}$.
