There are 7 pages in this quiz, including this one. In addition, 1 tear-off sheet is provided at the end.

As always, open book, open notes, open just about everything.

Problem 1: Support Vectors (50 points)

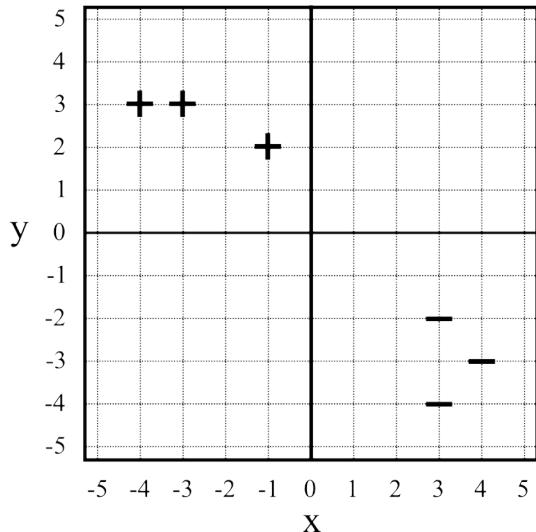

Part A (30 points)

The following three graphs represent the training data for two-dimensional, linear SVMs. + symbols indicate the coordinates of positive examples, which the classifier should give a value of 1 or more, and - symbols represent the coordinates of negative examples, which the classifier should give a value of -1 or less.

For each graph, you should do the following **three** things:

- Circle the support vectors
- Draw the “street” produced by the SVM, with solid lines where the classifier outputs 1 or -1 and a dashed line where the classifier outputs 0
- Describe the classifier function $h(\mathbf{x}) = \mathbf{w} \cdot \mathbf{x} + b$, by giving the values of \mathbf{w} and b

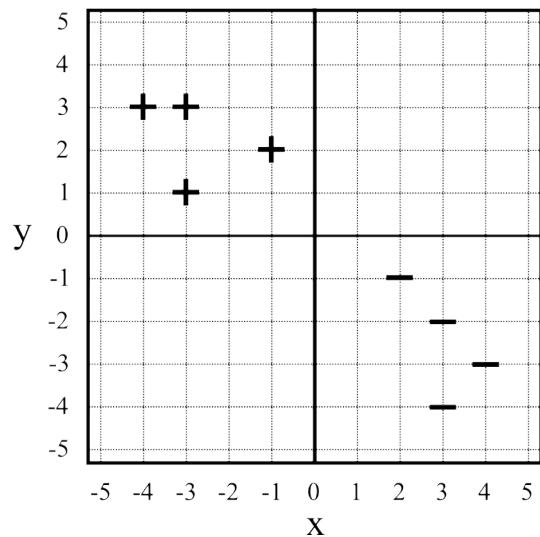

Graph #1

$$\mathbf{w} =$$

$$b =$$

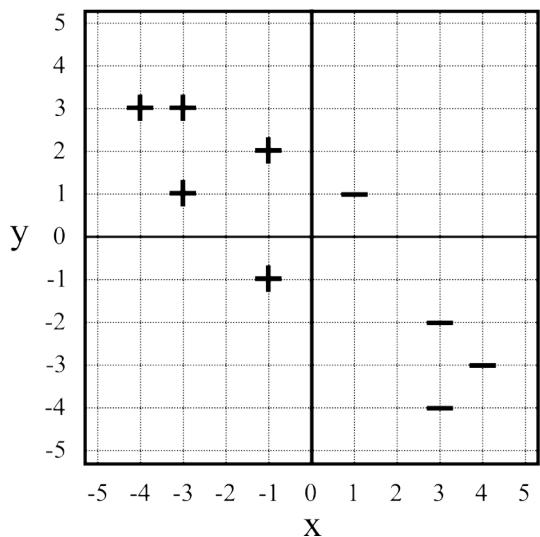

Graph #2

$$\mathbf{w} =$$

$$b =$$

Graph #3

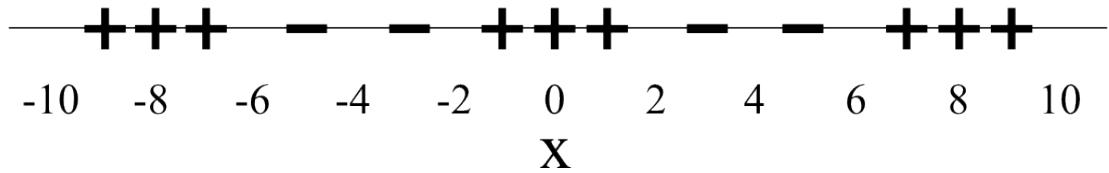

$$\mathbf{w} =$$

$$b =$$

Part B (20 points)

Susan Q. Randomstudent is frustrated by the data she is supposed to classify with a support vector machine. It's all on the same line, defined only by an x -coordinate, and it switches back and forth from clusters of + points to clusters of - points several times, so it's not at all linearly separable.

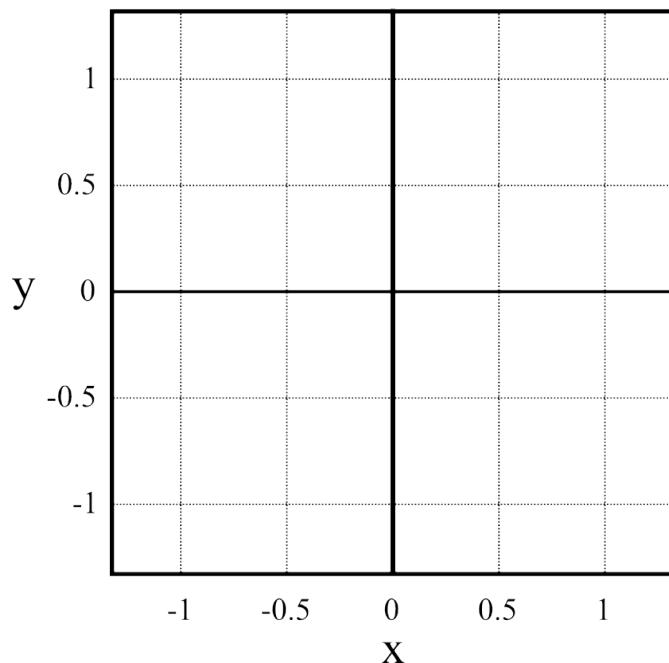

Eventually, though, she figures out a kernel function that she can use to separate the data:

$$K(x_1, x_2) = \cos\left(\frac{\pi}{4}x_1\right)\cos\left(\frac{\pi}{4}x_2\right) + \sin\left(\frac{\pi}{4}x_1\right)\sin\left(\frac{\pi}{4}x_2\right)$$

1. What is the Φ function that projects x into the new space defined by this kernel? (The function should take in x and output a vector with two components.)

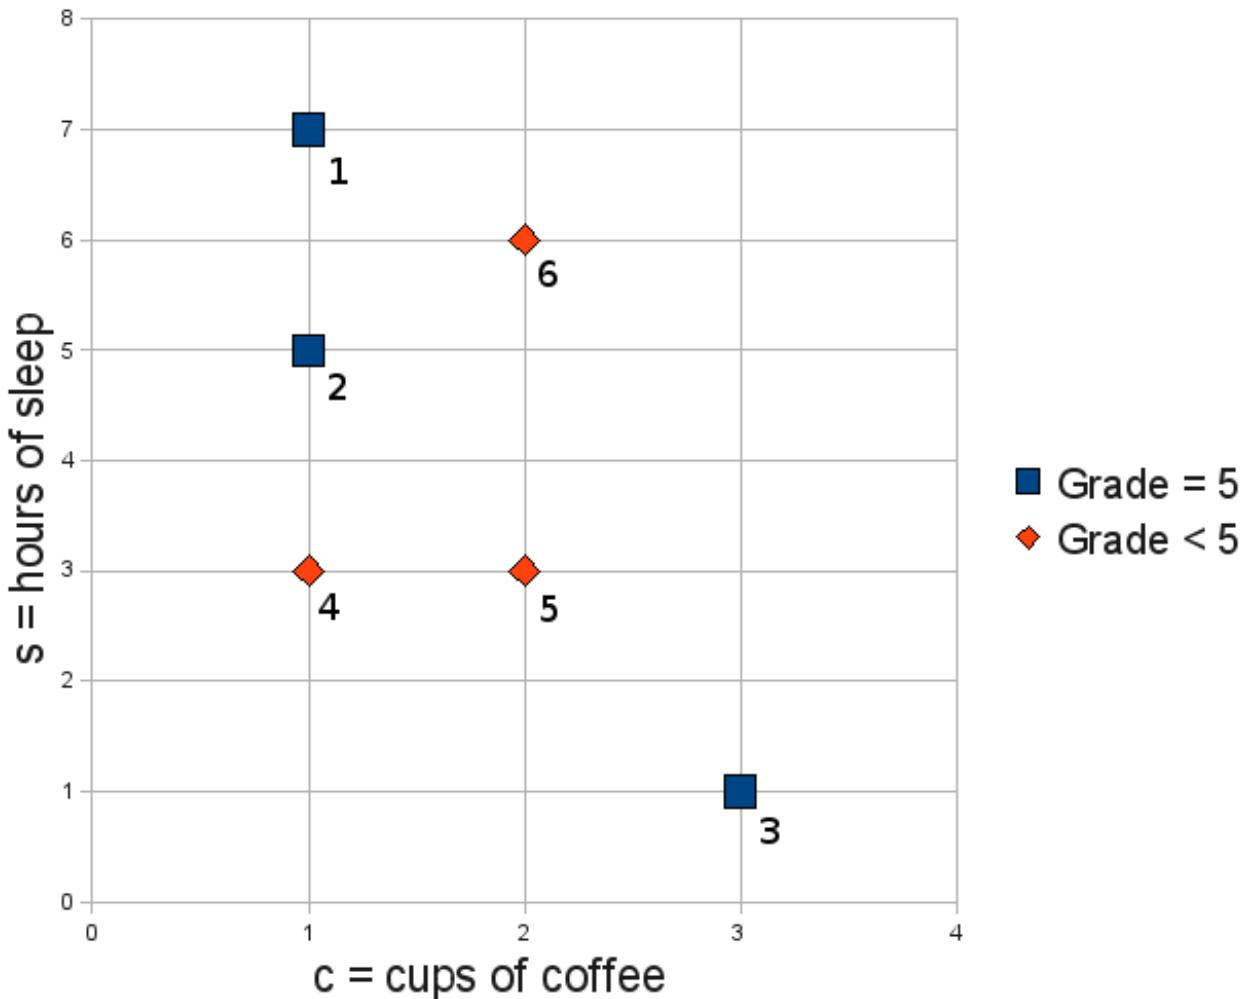

$$\Phi(x) =$$

2. On the grid below, draw the + and - points in the new space, and draw the “street” that linearly separates them.

Problem 2: Boosting (50 points)

Prof. Winston wants you to study the link between sleep, coffee, and 6.034 quiz grades. He gathered 6 data points from the previous quiz for you:

You decide to encode “Grade = 5” as +1, and “Grade < 5” as -1.

For this entire problem, consider only horizontal and vertical classifier stumps halfway between two data points, e.g. $h(c,s) = \text{sign}(c - 2.5)$ or $h(c,s) = \text{sign}(2 - s)$. You may also use $h(c,s) = +1$ and $h(c,s) = -1$.

In case of ties: prefer stumps involving s (horizontal) over stumps involving c (vertical), and prefer lower thresholds ($s < 1.5$) over higher ($s < 2.5$). Blanket classifiers $h(c,s) = +1$ and $h(c,s) = -1$ come last.

Part A (30 points)

Use Adaboost for 3 rounds. First update the weights using the results of the previous round, find the best stump $h(c,s)$ and its error ϵ . The starting weights have been filled in for you.

$$w_1 = 1/6$$

$$w_2 = 1/6$$

$$w_3 = 1/6$$

$$w_4 = 1/6$$

$$w_5 = 1/6$$

$$w_6 = 1/6$$

$$h_1(c,s) =$$

$$\epsilon_1 =$$

$$w_1 =$$

$$w_2 =$$

$$w_3 =$$

$$w_4 =$$

$$w_5 =$$

$$w_6 =$$

$$h_2(c,s) =$$

$$\epsilon_2 =$$

$$w_1 =$$

$$w_2 =$$

$$w_3 =$$

$$w_4 =$$

$$w_5 =$$

$$w_6 =$$

$$h_3(c,s) =$$

$$\epsilon_3 =$$

Part B (15 points)

What is the current Adaboost classifier made from combining these first three stumps? How many errors does it make on the training data?

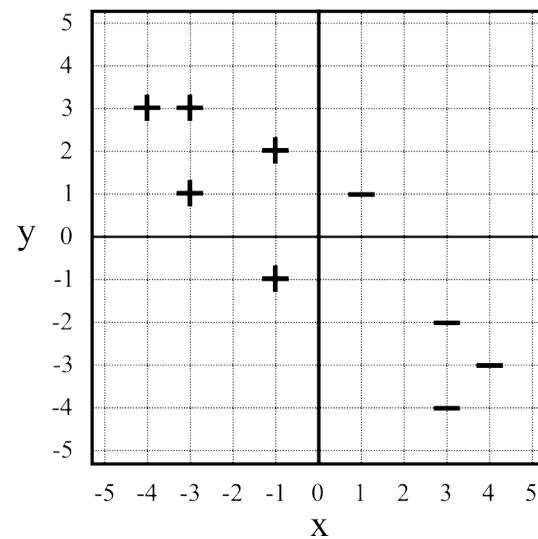

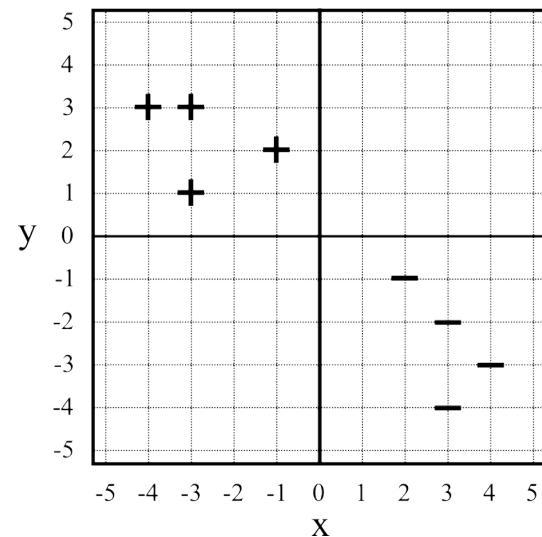

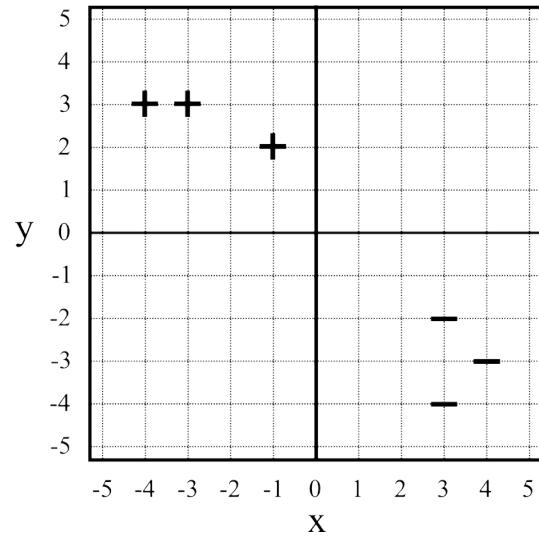

$$H(c,s) =$$

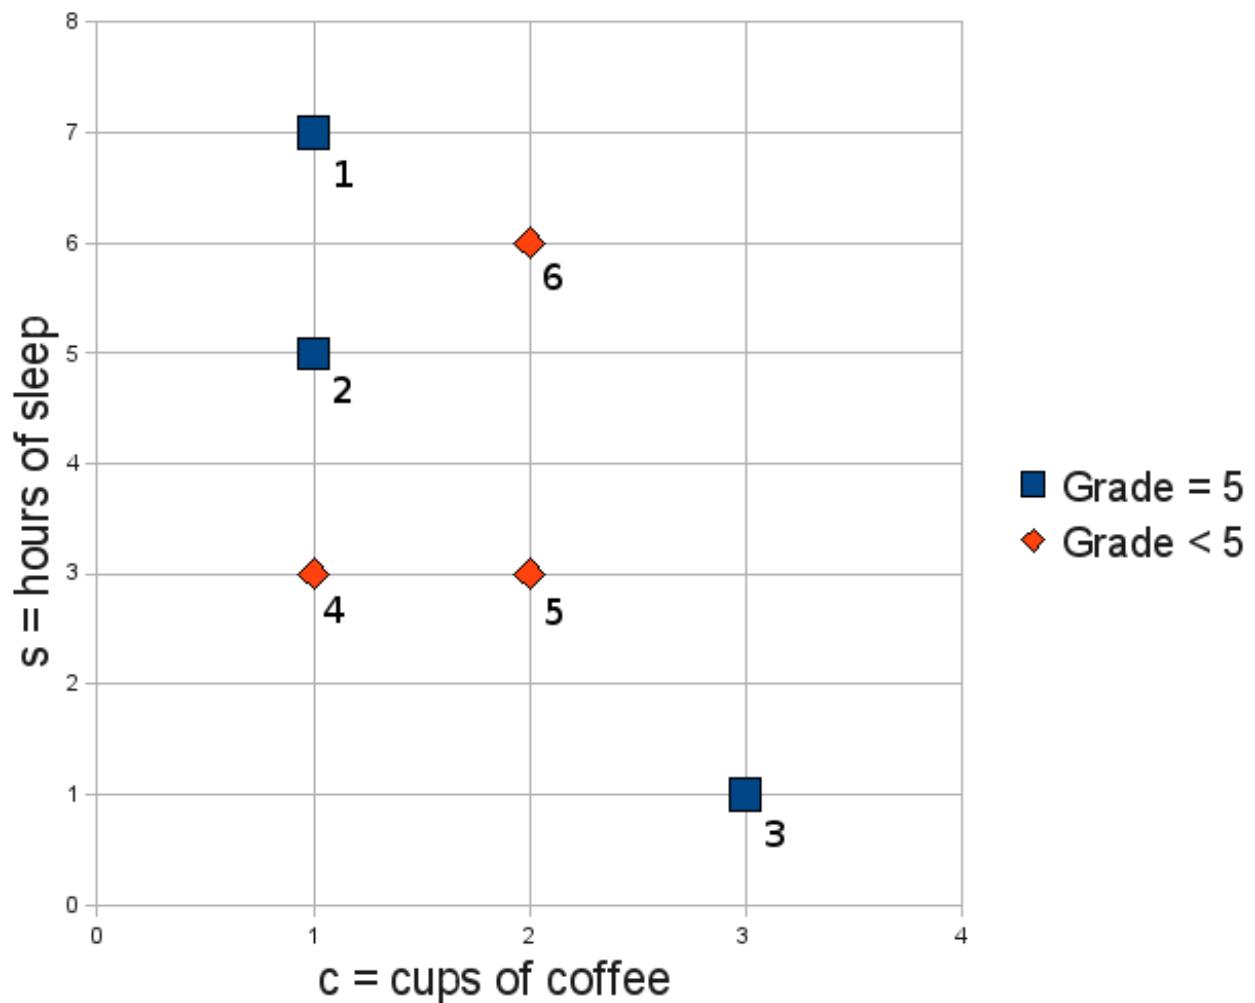

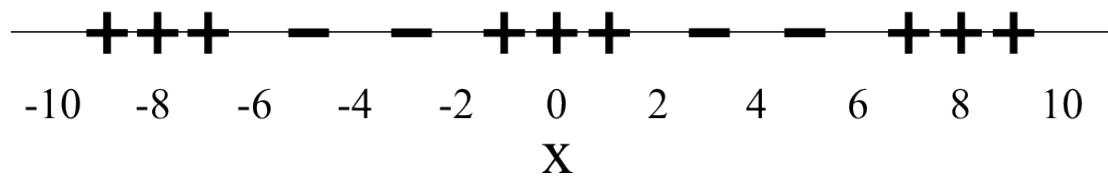

$$\# \text{ of errors} =$$

Part C (5 points)

If you were to run Adaboost for 100 more rounds, which data point or data points do you expect to have the **least** weight? Explain briefly. (You may write down another 100 rounds as in Part A in lieu of explanation.)

(This page is blank for a very good reason.)
