

Computing the Fourier Transform

We find the expansion coefficients, $A(\mathbf{q})$, by computing the Fourier transform of the wave packet in x -space. The Fourier transform is defined in terms of continuous variables \mathbf{x} and \mathbf{q} . To implement this in MATLAB® we need to approximate

$$A(\mathbf{q}) = \mathcal{F}(\Psi(\mathbf{x})) = \int_{-\infty}^{+\infty} e^{-i\mathbf{q}\mathbf{x}} \Psi(\mathbf{x}) d\mathbf{x}$$

by use of the discrete equation

$$\mathcal{F}(\Psi(\mathbf{x})) \approx \sum_{\{\mathbf{x}\}} e^{-i\mathbf{q}\mathbf{x}} \Psi(\mathbf{x}) \delta\mathbf{x}$$

To do this, we create a vector with all of our x values, i.e.:

$$\vec{x} = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_n \end{pmatrix}$$

Similarly, we define a vector with all the values of $\Psi(\mathbf{x})$:

$$\vec{\Psi}(\mathbf{x}) = \begin{pmatrix} \Psi(x_1) \\ \Psi(x_2) \\ \Psi(x_3) \\ \vdots \\ \Psi(x_n) \end{pmatrix}$$

We then define a vector for our reciprocal space:

$$\vec{q} = \begin{pmatrix} q_1 \\ q_2 \\ q_3 \\ \vdots \\ q_m \end{pmatrix}$$

The values for \vec{q} are determined by the properties of the discrete Fourier transform. Note, in general, \vec{x} and \vec{q} do not contain the same number of elements, i.e. $m \neq n$.

Now, the outer product of \vec{x} and \vec{q}^T is

$$\vec{x} * \vec{q}^T = \begin{pmatrix} x_1 q_1 & x_1 q_2 & \dots & x_1 q_m \\ x_2 q_1 & x_2 q_2 & \dots & x_2 q_m \\ \vdots & \vdots & \ddots & \vdots \\ x_n q_1 & x_n q_2 & \dots & x_n q_m \end{pmatrix}$$

Taking the exponential of \mathbf{i} times each element of the above matrix yields:

$$\vec{\phi}_{\vec{q}}(\vec{x}) = e^{i\vec{x} \cdot \vec{q}} = \begin{pmatrix} e^{ix_1 q_1} & e^{ix_1 q_2} & \dots & e^{ix_1 q_n} \\ e^{ix_2 q_1} & e^{ix_2 q_2} & \dots & e^{ix_2 q_n} \\ \vdots & \vdots & \ddots & \vdots \\ e^{ix_n q_1} & e^{ix_n q_2} & \dots & e^{ix_n q_n} \end{pmatrix}$$

Note, the MATLAB® command ``exp'' takes the exponent of each element in a matrix.

Then,

$$\begin{aligned} \vec{A}(\vec{q}) &= \sum_{\{\mathbf{x}\}} \vec{\phi}_{\vec{q}}(\mathbf{x}) \vec{\Psi}(\mathbf{x}) \delta \mathbf{x} \\ &= \vec{\phi}_{\vec{q}}^\dagger(\vec{x}) * \vec{\Psi}(\vec{x}) \delta \mathbf{x} \\ &= \begin{pmatrix} e^{ix_1 q_1} & e^{ix_1 q_2} & \dots & e^{ix_1 q_n} \\ e^{ix_2 q_1} & e^{ix_2 q_2} & \dots & e^{ix_2 q_n} \\ \vdots & \vdots & \ddots & \vdots \\ e^{ix_n q_1} & e^{ix_n q_2} & \dots & e^{ix_n q_n} \end{pmatrix}^\dagger * \begin{pmatrix} \Psi(x_1) \\ \Psi(x_2) \\ \Psi(x_3) \\ \vdots \\ \Psi(x_n) \end{pmatrix} \delta \mathbf{x} \\ &= \begin{pmatrix} e^{-iq_1 x_1} & e^{-iq_1 x_2} & \dots & e^{-iq_1 x_n} \\ e^{-iq_2 x_1} & e^{-iq_2 x_2} & \dots & e^{-iq_2 x_n} \\ \vdots & \vdots & \ddots & \vdots \\ e^{-iq_n x_1} & e^{-iq_n x_2} & \dots & e^{-iq_n x_n} \end{pmatrix} * \begin{pmatrix} \Psi(x_1) \\ \Psi(x_2) \\ \Psi(x_3) \\ \vdots \\ \Psi(x_n) \end{pmatrix} \delta \mathbf{x} \\ &= \begin{pmatrix} \Psi(x_1)e^{-iq_1 x_1} + \Psi(x_2)e^{-iq_1 x_2} + \dots + \Psi(x_n)e^{-iq_1 x_n} \\ \Psi(x_1)e^{-iq_2 x_1} + \Psi(x_2)e^{-iq_2 x_2} + \dots + \Psi(x_n)e^{-iq_2 x_n} \\ \vdots \\ \Psi(x_1)e^{-iq_n x_1} + \Psi(x_2)e^{-iq_n x_2} + \dots + \Psi(x_n)e^{-iq_n x_n} \end{pmatrix} \delta \mathbf{x} \end{aligned}$$

i.e. a vector indexed by \mathbf{q} which contains the sum we defined to be an approximation to the Fourier transform, known as the Discrete Fourier Transform (DFT).
