Glossary
The 6.001 Lab and other Scheme Implementations

Important Information

Please make special note of the following points:

- If you are working on a project (as opposed to an online problem set) read the entire project BEFORE you begin your work. Often, a question you have will be explained in a later section of the problem set.
- Browse the 6.001 Web page regularly. It contains course handouts, announcements, Scheme software, documentation, advice on where to get help, and other useful information.
- Read section Logging In, for information about logging in for the first time in the 6.001 lab.

We have put this information here in case you decide not to read this entire guide. Generally, this manual is organized on a "learn-as-you-go" basis. Anything that is not essential to doing a project or problem set is not explained here; however, we will describe how you can find additional information on-line. Although this extra information might not be necessary to complete the problem sets, it will make the programming easier and so we urge you to explore.

Scheme Implementations for 6.001

The 6.001 Lab is reserved for the exclusive use of students in 6.001. You'll find it convenient to work here because the Lab Assistants are available to help you, and you can share the warmth and camaraderie of your classmates while you work on problem sets. If you want to use your own computer, the 6.001 staff provides implementations of Scheme for Linux, Windows NT 4, and Windows 95 (sorry, no Macs). See the tools section for software and installation instructions.

The problem sets and projects are designed so that they should run on all of these implementations, and you can move your work between them if you find this useful. For example, you might start problem set at home, then spend some time debugging it in the lab where the Lab Assistants can help you, and then finish things up at home.

6.001 is not officially supported on the MIT server. The implementation of Scheme on the MIT server that runs on Linux machines should be compatible with the 6.001 implementations, although we do not guarantee that it can run all the problem sets. Other versions of Scheme on the MIT server are likely not to be compatible with 6.001.

The lab machines are set up as MIT server machines in the following manner, however. They will automatically save all your work in your MIT server home directory (in ~/u6001/work by default). You can...
Don't Panic

perform most MIT server operations on these machines. Please note that this is not a supported MIT server platform, so don't bug I/S employees with problems. Send all bug reports, comments, and questions about the lab setup to the TA.

Lab Location

Since the door outside the 6.001/.004 lab has an electronic lock, you will want to bring along the combination, which is given out in lecture. Make sure you also bring your textbook, this guide, and a copy of the project if that is what you are planning to work on.

Lab Assistants

Lab Assistants (LAs) are an integral part of the 6.001 lab. They make sure that everything runs smoothly by maintaining hardware and fixing certain problems so that the lab is available to as many students as possible. However, LAs are not in the lab just to maintain hardware; their real purpose is to offer you assistance on problems that you encounter while trying to do the problem sets. If you get stuck, check the blackboard for the help queue status. If the queue is on, write the name of your machine in the next available space. If the queue is off, look for an LA walking around or using a computer to assist you.

Don't think that you must have a major problem to ask for help. Although the LAs are not there to write your code for you, they can assist you when you stop making progress on your problem set. The best way to make sure that all of your questions get answered is to get to the lab early in the week. The night before the problems set is due is not a good time to ask an LA to explain a complicated issue. Instead, come to the lab early or make an office appointment with your recitation instructor or TA if you begin having difficulties. The lab will be very busy the night before the problem set.

If you notice hardware problems, you should contact one of the LAs on duty. If one is not in the room, place a note by the computer that explains what you think the problem is and when you noticed it. If an extreme problem occurs (like a fire) when an LA is not around, contact someone at the equipment desk located outside of the lab.

The Scheme of Things

The 6.001 text book describes how to program in Scheme but it gives none of the details of how these programs are entered into the computer, tested and changed. This chapter describes the basic things that happen when you use the computer.

Flow of Control
Control of the computer begins with you. You can direct the computer by moving the mouse or by typing at the keyboard. These keystrokes and mouse actions are first inspected by a program called the "window manager" to see if you are requesting that it perform some operation. The window manager then passes your keystrokes to the application that has the focus (the highlighted window has the focus). Ordinarily, the only application that you see is Edwin, a text editor very similar to Emacs. You will usually want Edwin to have the focus. You can tell the window manager to give Edwin the focus by clicking the mouse on the border surrounding the Edwin window. This should make the border a different color (whatever the default is for your machine) and allow Edwin to receive your keystrokes.

A text editor is a program that allows you to compose text (programs, memos, letters, books, etc.) much as you would with a typewriter. Unlike a typewriter, Edwin will allow you to modify text that you have already written so that you don't have to type it in all over again. Edwin also allows you to work on more than one piece of text at a time, each in its own buffer.

Be sure to save your files before quitting. Otherwise your work will be lost.

Once you have written your programs using Edwin, you can instruct Edwin to send them to the Scheme interpreter and record the results. Although almost any buffer can send expressions to the Scheme interpreter, the Scheme interpreter writes its responses only into the `*scheme*` buffer. The `*scheme*` buffer is the default buffer that Edwin displays when you first log in.

**Special Buffers**

Here is a short list of most of the buffers that you will working with:

`*scheme*`

This is the buffer where you get responses from the Scheme interpreter. Also, you should evaluate test expressions in this buffer. Note, however, you should really only use this buffer for evaluating test expressions. Do the modifying of your code in a separate code buffer.

`*transcript*`

This buffer also gets all the responses from the Scheme interpreter. It differs from the `*scheme*` buffer in that you are not meant to type expressions here. Like a "black-box", think of it more as a diary of what has taken place since you have logged in. You copy text out of this buffer to make a transcript. You very rarely want to type things into this buffer.

*Project Code Buffers*

These buffers contain the code that makes the projects do their magic. Normally they are read-only signifying that you should not change them. If it becomes necessary for you to change the code in one of these buffers, copy only those parts which you need to change into your answer buffer.

*Answer Code Buffers*
This is where you spend time writing programs. Normally your answer buffers end with `.scm' which tells Edwin that the contents of the buffer is Scheme code. Usually you only need one answer buffer per project for code but using additional buffers to store partial transcripts and comments to yourself is very useful. You will also want your answer buffers to correspond to a file in your directory.

**Standard Conventions**

We have already told you enough about communicating with the window manager to get you through 6.001. Obviously, much more will be said about communicating with Edwin and thus the Scheme interpreter.

Normally, pressing an alphanumeric key tells Edwin to insert a character in the current buffer. However, you can press special keys in combination with normal keys to give Edwin commands. Most of these keys are now standard parts of keyboards. Thus, the Control key is located next to the `a' key. It works like the shift key meaning that you should hold it down while pressing another key. For example, when we say C-x we mean: hold down the key labeled CTRL while you press `x'. The Meta key also works like the shift key. If this is not explicitly labeled as Meta then it will typically be the Alt key, located to the left of the keyboard. When we say M-x, we mean hold down the Meta key while you press `x'. Sometimes it is necessary to hold down both CTRL and META at the same time. When we want you to do this, we will say C-M-x.

Some commands take immediate effect while others wait for you to type a response to a question posted in the mini-buffer. At this point, pressing just one more key will sometimes cause the command to take effect. Otherwise, Edwin expects you to type a few words into the mini-buffer and press RET to tell Edwin when you are done. For more information, see section The Mini-buffer.

Like Meta and Control, there are other keys that we refer to with special abbreviations.

- **TAB**
  - the tab key
- **RET**
  - the Return key
- **SPC**
  - space or the space-bar
- **LFD**
  - line-feed or C-j
- **ESC**
  - the escape key

**Logging In and Loading Project Code**
Logging In

Use your MIT server username and password to log in. If you don't have an MIT server account yet (because you have Special Student status, are cross-registered, etc), go to the MIT server Accounts office's front desk. Their hours are:

- Monday, Wednesday, Friday ...................... 2:00pm - 5:00pm
- Tuesday, Thursday .............................. 9:00am - 12:00pm

The MIT server proceeds as normal. To run Scheme, do

```lisp
add 6.001
6001-scheme &
```

Loading Problem Sets

Normally, you will just use the online tutor to deal with problem sets. You may find it convenient, however, to use your own Scheme environment to experiment with your answer. In this case, you should be able to cut-and-paste your answer from your Scheme environment into the tutor's window for submission. In those cases where a problem set has supporting code, we will provide a link from the tutor page that will enable you to access that code.

Loading Project Code

Projects will involve more extensive coding that problem sets, and for this we will provide a mechanism for letting you get access to that code. For historical reasons, the command is `M-x load-problem-set`. Edwin prompts you for the project number in the mini-buffer. Edwin should also show a default project in parentheses. To select the default just type `RET`. Otherwise, enter the correct project number and then hit `RET`.

If you are working on your own computer, and starting a new project, you'll need to download the project files to the correct directory on your own machine. After that, `M-x load-problem-set` will work as above. You'll find the project files, together with instructions for downloading them, on the course web site.

Editing Your Code

Edwin normally displays the `*scheme*` buffer, the mode line, and the mini-buffer when it starts up.
The mode line tells you useful information like the name of the buffer above it and whether that buffer is read-only, modified or unmodified. It has the following appearance:

```
--ch-Edwin:  buffer       (major minor)----pos----------
```

The italicized fields have the following meaning:

- **ch**
  - is `**' if the text has been modified or `--' if the buffer has not been modified since last being saved. A read-only buffer contains `%%' in this field.

- **buffer**
  - is the name of the buffer.

- **major**
  - is the major mode of the buffer. For example, most buffers contain "Scheme" here.

- **minor** (an optional field)
  - is the minor mode of the buffer. For example, "Fill" appears when a buffer is in auto-fill mode.

- **pos**
  - is information about the position of the point in the buffer. This field may be either `All', `Top', `Bot', or a percentage.

The `*scheme*` buffer and any buffer that ends with `.scm` have an additional field, the **run-light**, to tell you whether it is currently evaluating a Scheme expression. For example:

```
---**-Edwin: *scheme*          (REPL: listen)----ALL----------
```

means that Edwin is ready to evaluate something. Edwin changes **listen** to **eval** when it is busy evaluating an expression. If Edwin has been evaluating for a long time and you would like to stop it, type `C-c C-c` to interrupt the Scheme interpreter and get back to "listen" status.

The mini-buffer is the bottom line in the Edwin window. It is used for communicating with Edwin when you request certain commands. For example, when you visit a file, Edwin prompts you for the file's name in the mini-buffer.

The commands you will use most often will deal with editing your code. We will briefly describe those commands in this chapter.

## Loading a File into a Buffer

In order to modify a file or to create a new one, you must first instruct Edwin to "visit" the file. Do this by typing `C-x C-f file-name`. This will cause Edwin to create a new buffer and place the contents
of the file into it. If the file does not exist, Edwin will make an empty buffer and allow you to edit that instead. If you didn't want to start a new file, type `C-x k RET` to kill the buffer and try again.

## Switching Between Buffers

Once you have a few buffers in memory, you will want to switch between them quite often. Typing `C-x b buffer-name` allows you to enter the name of the buffer that you would like to switch to. It will also display a default buffer that you may select by pressing return.

`C-x C-b` switches you to the `*buffer list*` buffer. This buffer isn't meant for editing text. Instead, you use `*buffer list*` to select buffers from a list of all the buffers that Edwin knows about. You may use the cursor keys to move to the line of the buffer and press `f` to select it.

Other commands have a natural side effect of moving you to a new buffer. For example `C-x k` will kill the current buffer and then place you into the previous buffer. Remember that if you kill a buffer without saving it, all of your changes will be lost. Edwin will warn you if you try to kill an unsaved buffer, and give you a chance to back out of the command. If you really want to kill the buffer without saving your changes, type `yes`.

### The Mini-buffer

The mini-buffer is the last line of the Edwin window where Edwin sometimes expects you to type responses to questions that it asks. There are two things that you should know about the mini-buffer. First of all, pressing `C-g` will exit the mini-buffer at any time. Second, pressing `SPC` or `TAB` while in the mini-buffer will generally cause Edwin to try to complete what you have begun to type. If you have typed a unique prefix to a word, then Edwin will complete that word. Otherwise, Edwin will list all of the possible completions to your prefix. You may then type just enough characters to give you the command, file, or buffer that you really want. This feature of Edwin will save you countless keystrokes.

To learn how Edwin can complete Scheme procedure and variable names, see section [Completion for Scheme Symbols](#).

## Editing A Buffer

### What you should and should not edit

In general, you should never change the buffers that contain read-only code given to you in the problem sets, nor should you change the `*transcript*` buffer. If you want to change these buffers, you should copy the sections you want into one of your buffers first (see section [Using the Region to Copy or Move Text](#)). Otherwise, you will end up with tiny changes that no one will be able to find. This will make your code much more difficult to debug.
Inserting Letters and Moving The Point

Once you are in the buffer you want to edit, typing characters causes text to be inserted into the buffer at the point (the little reverse-video box), but nothing is overwritten. If you would like to delete a character or two use Back space to remove the character to the left of the point and C-d to delete to the right of the point. If you want to delete a whole line, use C-k to erase all the text right of the point on the current line (C-y will bring the text back if you make a mistake).

The cursor motion keys (the keys with triangles on them) allow you to move the point to a new location and begin inserting characters there. There are also commands that allow you to move the point around much faster over larger areas. C-v will move the point down an entire screen while M-v will move the point up by the same amount. C-e will move the point to the end of a line while C-a will move it to the beginning. Refer to the on-line documentation for more commands to move the point around.

Undoing Mistakes

If you make a mistake while editing your code, type C-x u. Edwin remembers about 8000 characters worth of changes that it will allow you to undo. Consecutive repetitions of C-x u will cause Edwin to undo older and older changes. Any command other than an undo breaks the sequence. At this point C-x u will allow you to undo your undos, known as redoing an undo.

If you really mess up, it is sometimes desirable to restore the buffer to the way it was the last time you saved it. You can do this by typing M-x revert-buffer.

Using the Region to Copy or Move Text

Many Edwin commands operate on a region of text. First you set up the region and then you type a command to operate on it. You begin the region by setting up what is known as the mark. To do this, move to the beginning of the text that you want to define as the region and then press C-SPC. Next move the point to where you want the region to end and invoke a command. For example, C-w will delete the region and place it into what is affectionately called the kill ring. You can get this text back by typing C-y. Also, you can type M-w which will place a copy of the text into the kill ring without deleting it. You can also extract this copy with C-y. To find out where the mark is at any time, press C-x C-x which swaps the point and the mark. Pressing C-x C-x again will swap the point and mark back.

Saving A Buffer

You should save your answer buffers periodically so that if the computer crashes, you do not lose all your work. This is done by typing C-x C-s. Also, be sure to save your buffers before you log out or
Don't Panic
quit the machine.

**Using Dired to Manage Your Files**

Generating all these files means that we will need some way to manage them. Edwin provides a command, `M-x dired`, for showing a visual representation of a directory of files. Dired creates a special buffer which you can not edit in the normal way. Instead, you have an easy way to rename files, to mark files for deletion, and to load files into buffers for editing. When you are in the Dired buffer, typing `C-h m` will display all of the commands available there.

To select a file for editing, move the point to the line of a file and then press `f`. This is like typing `C-x C-f file-name`. Pressing `o` will do nearly the same thing except that the file will be loaded into another text window and the Dired buffer will stay where it is.

To delete individual files, move the cursor to the correct line and press `d` and Edwin will place a `D` beside the file. You can unmark the file by pressing `u` when you are on the line. When you have marked all the files that you are sure you want to be deleted, press `x` and answer yes. Now when you checkpoint your disk or when you log out, Edwin will remove these files from your floppy drive too. If you accidentally erase a file talk to an LA because sometimes it is possible to recover lost files.

To delete backup copies of files with Dired, press `~` and all the backup files will have a D placed beside their names. Now pressing `x` will cause Edwin to ask you if you would like to delete these files. Type yes and then those files will be deleted. Again, the process isn't complete until you checkpoint your disk or log out.

**Running and Testing Your Code**

**Evaluating Code**

There are a few ways to evaluate code from a buffer. One way is to type `M-o`. This command tells Edwin to send the entire buffer to the Scheme interpreter to be evaluated. `M-o` is not defined in the `*scheme*` buffer. Another command, `M-z`, tells Edwin to only send the current definition to Scheme in order to be interpreted. A definition in this case is not necessarily an expression such as `(define (foobar baz) ...)`. Instead, Edwin searches backwards until it finds an open parenthesis on the left margin, searches forward to find its mate and evaluates the expression in between. This makes it convenient for all sorts of "top-level" expressions. A third way to evaluate expressions gives more control than either of the first two methods. `C-x C-e` evaluates the expression just before the point regardless of where it is in relation to all the parentheses.

Some people try to remember which definitions they have changed so that they only evaluate those
Don't Panic

portions of their program. This is often more trouble than it is worth because if you forget to update just a single definition, then a bug that you thought you just fixed still appears and you could be confused for a long time. If you always use \texttt{M-o} then your code will be up-to-date with what is written when you test it.

**The \texttt{*scheme*} buffer**

The most sensible place to test your code is in the `*scheme*` buffer. Typing a test case (a Scheme expression meant to test portions of your code) and then \texttt{M-z} or \texttt{C-x C-e} generates a nice listing of trial expressions and their results. If you would like to repeat a test case that you have evaluated already, \texttt{M-p} will allow you to cycle through your most recent expressions. Every time you press \texttt{M-p}, Edwin shows copies of older and older expressions that have been evaluated in the `*scheme*` buffer. When this history runs out, Edwin just starts over at the beginning. It is often the case that you would like to repeat the last evaluated expression with different arguments. There is a right and a wrong way to do this. The right way is to type \texttt{M-p}, edit the expression, and then type \texttt{C-x C-e}. The wrong way is to use the cursor keys to move up through the Scheme buffer and edit the previous expression in its original context. It is much faster and easier to use the history mechanism, and using it won't leave you with a confusing buffer, unlike direct editing.

Note, however, that we urge you to only use this buffer for evaluating test cases. Do the actual code development and modification in a separate code buffer. This way you can cleanly separate your work from its testing.

**Debugging**

When testing your code you will find that often it doesn't work as expected. Sometimes your code will stop dead in its tracks and produce an error message on the screen, sometimes it will return an incorrect result, and sometimes it won't return anything at all because it is caught in an infinite (or at least an unreasonably long) loop. These mistakes in your code are called bugs and getting rid of them is an art-form known as debugging.

The first kind of bug is often the easiest to fix. Sometimes you have just misspelled a variable or procedure name, or have misplaced a parenthesis. Usually your typos are obvious when the computer points them out to you. At other times the computer screams at you when your program is trying to do an illegal operation (like trying to add two procedures!). In cases like this, it is useful to enter the debugger and see what you can learn about the bug. Questions you should ask yourself are:

- How did my procedure get into this state?
- Do any variables have values that they clearly should not?
- Are all the procedures that I use in this procedure working correctly?
- Do I have the arguments in the correct order?
Don't Panic

- Am I using the correct variables?
- Does my procedure have a logical error?
- Did I remember to evaluate all the changes that I made?
- Did I do anything that would cause any old definitions to still be around?
- Did I write this code?

These are useful questions to ask no matter what kind of bugs you have. Remember that even if your procedure seems to work with one or two test cases, you could still have errors in it. Make sure to test the boundary conditions (if you don't your TA will). For example, maybe you forgot to test your absolute value procedure with the number zero. Question: how many fence posts do you need to buy to make 100 feet of fence with a fence post every 10 feet? If you quickly answered 10, then you are especially susceptible to fence-post errors. Otherwise, see how many of your friends will fall for this one.

Only experience can help you become a master debugger. Often the first thing that a beginner does when he or she gets an error message is to type `q` to avoid entering the debugger. This violates a very important rule of debugging: don't throw away information. So when you get an error, go ahead and see what information you can gather.

If the debugger doesn't give you the needed information, sometimes it is useful to put a display expression into your code to gather information. Also, you may make your procedures robust so that when they get illegal values, they give you information that the debugger wouldn't give you. These two methods are especially useful with the never-ending-procedure variety of bugs.

A more useful way to gather information is to use the procedure `error`. `error` displays its first argument which should be a string and then displays the rest of its arguments which are any objects of special concern to debugging. Then you are asked if you would like to enter the debugger. Here is an example:

```scheme
(define (cube x)
  (if (not (number? x))
      (error "Argument should be a number instead of" x)
      (* x x x)))
;cube --> #[compound-procedure 28 cube]
;Value: #[undefined-value]

(cube 'hi)
;Argument should be a number instead of hi
;Type D to debug error, Q to quit back to REP loop:
```

One of the best ways of debugging code is to get a lab assistant to help you. Even if they can't immediately find your bug, they can probably tell you whether what you are trying to do is a good idea.
Another powerful debugging technique is to completely rewrite some of your code in an improved way. It is often easier to avoid bugs than to find them so use a clear design instead of clever or tricky code that is sure to fail during the next waning crescent. However, if you enjoy debugging code, feel free to make lots of mistakes so that you can find them later.

For more information on using the debugger, see section Debugger.

**Stepper**

If you type an expression in `*scheme*' buffer and, instead of evaluating it with `C-x C-e`, type `M-s`, Edwin will invoke the Scheme stepper, which permits you to go through step through evaluation of the expression element by element and see the evaluation of each subexpression.

In general, you use the debugger and stepper to home in on bugs from two different "directions." If you have a program that signals an error, you can just let the error occur and use the debugger to try to figure out what happened; or you can step through the program up to the point where you see the error happen and try to figure out what is causing it.

To exit from the stepper, simply kill the stepper buffer.

**Using On-Line Documentation**

There are different forms of on-line documentation. Some on-line documentation is meant to teach you skills. For example, the Edwin tutorial is an interactive tutorial useful for when you first begin using Edwin. It is accessed by typing `C-h t`.

Most of the on-line documentation is meant to be used as reference material. This is available through web from the 6.001 home page. The documentation files are included with the 6.001 distributions as HTML files that you can read locally with a web browser if you are using your own computer and are not connected to the network.

**What is Especially Useful**

Here is a short summary of the on-line information available off the MIT server.

`Don't Panic`
- This manual in its on-line incarnation.
`Scheme Reference Manual`
- This is the MIT Scheme Reference Manual. It documents the special forms and procedures that
Don't Panic

are available in MIT Scheme.

`Scheme User's Manual'
This has some details on MIT Scheme and Edwin.

`R4RS'
The Revised Report on the Algorithmic Language Scheme is the official (and not very readable) specification of the Scheme language.

## Printing

### Printing A Buffer

To print out a buffer type `M-x print-buffer`. Remember to get your print-out right away or it may get lost in a huge heap of paper. The header has the machine name on it.

Alternatively, from a top level window, use the Linux commands to print a buffer:

```
cd ~/u6001/work
lpr project1.scm
```

will for example connect to your work directory, then print out the Scheme file (note the `.scm` extension) titled `project1`.

## Making A Transcript

The easiest way to get a transcript is to copy text from the `*transcript*` buffer and accumulate it into another buffer. You should remove the test cases that you do not wish to keep and place your name and other information including the problem set number and the exercise at the top. You might also want to make special comments about some of the test cases. When you are done with the entire problem set, you can print out this buffer. It's a good idea to comment the transcript after each problem, while the details are still in your mind. Incrementally building your final transcript takes less effort than doing it all at the end.

## Logging Out and Giving Feedback

### Logging Out

To logout, make sure your have saved all of your files and then type `M-x logout`. Note that the standard quit command: `C-x C-c` also works. If you have forgotten to save any of your buffers,
Edwin will give you a chance to do it now. If you still don't save all of the buffers, Edwin will say "Modified buffers exist. Exit anyway?" If you don't want to save these buffers then answer yes. Now Edwin will checkpoint your floppy disk. Edwin will ask if you want to kill Scheme. Type yes if you really want to exit Edwin and Scheme and return to the main Login screen. Now you should take the floppy disk out of the floppy drive. If you do leave something behind in the lab and can't find it later, check the lost and found box near the front of the lab.

Feedback

If you find any bugs, or problems dealing with the lab, send mail to the TA.

Common Problems and Solutions

If you have any problems that aren't listed here, please pass them along to us so that we can include them in the next printing of this document. For directions on doing this, see section Feedback.

Edwin won't respond to anything I type!

One cause of this is that Edwin is not receiving any keystrokes from the window manager. If this is the case, the border around Edwin will be light grey instead of dark grey. To fix this problem, click the left mouse button when the cursor is in the border of the Edwin window.

How Can I Reach a "Steady State?"

Often times you will lose and just want to return to some sort of steady state so that you can continue to do your work. If all of a sudden you do something that seems to trash half of your buffer, stop and relax. The first thing that you should try is \texttt{C-x u}, the undo command. If this fails to do any good, you might try performing a yank using \texttt{C-y}. If neither of these seems to work, use the write command, \texttt{C-x C-w} which will allow you to save the buffer under a different name. Now you can load up the old version using \texttt{C-x C-f}. Next, visually compare these two buffers to see if you can recover any recent changes. You might also want to save your buffers often so that you can always restore to a steady state by doing \texttt{M-x revert-buffer}. If your problem is that Edwin does not seem to be evaluating things
properly, try typing \texttt{C-c C-c} a few times. Look at the mode line in the \texttt{*scheme*} buffer and make sure you see the word "listen" which means that Scheme is ready to accept expressions. For really drastic problems, try saving all of your buffers that don't seem screwed up and logging out. When you log back in, things should be back to normal. If this doesn't help then it is time to talk to an LA.

\section*{Edwin Major Modes for Scheme}

Edwin uses major modes to determine which keyboard commands are available in a buffer. Edwin defines two major modes that facilitate the writing and testing of Scheme programs. The REPL major mode is the default mode of the \texttt{*scheme*} buffer and Scheme mode is normally used in buffers of Scheme source code. REPL and Scheme mode are very similar to each other and to the Emacs LISP major modes. REPL and Scheme modes include the editing commands from fundamental mode and enhance these with more commands for evaluating Scheme expressions.

\section*{Scheme Mode}

The Scheme major mode is specialized for editing Scheme code. It adds indentation and evaluation commands to the normal array of editing commands.

\begin{itemize}
  \item \texttt{\textbf{TAB}}\quad indent the current line for Scheme.
  \item \texttt{C-M-q}\quad indent the next expression.
\end{itemize}

The following commands evaluate Scheme expressions:

\begin{itemize}
  \item \texttt{M-ESCAPE} \quad Read and evaluate an expression in mini-buffer (eval-expression).
  \item \texttt{M-z} \quad Evaluate the current definition (eval-defun).
  \item \texttt{C-x C-e} \quad Evaluate the expression preceding point, placing the result in the \texttt{*scheme*} buffer (eval-last-sexp).
  \item \texttt{M-o} \quad Evaluate the buffer (eval-current-buffer).
  \item \texttt{C-M-z} \quad Evaluate the current region (eval-region).
\end{itemize}

\texttt{TAB} indents the current line to show the nesting of parentheses. Pressing \texttt{TAB} anywhere on a line has the same effect: attractive source files that make parenthesis-balancing clear.
C-M-q is a great way to indent the current definition. Move to the beginning of the current definition (using C-M-a) before you use this command.

M-z is the work horse evaluation command in a REPL buffer, but it is also useful in a Scheme buffer. M-z looks backwards to find an expression that starts on the left margin and then evaluates it.

For more precise control over what is evaluated, use C-x C-e. C-x C-e evaluates the expression before the point regardless of where it is in a parenthesized structure. Unlike M-z, it is not meant for evaluating just top-level expressions (more importantly, it can evaluate expressions that are not combinations).

M-o evaluates the buffer, which is useful because it insures that all of your changes are evaluated. To make this command even more useful, you should refrain from putting procedure definitions and operations that are meant to test these procedures in the same source file. For example, if you have the fibonacci definition in a file along with (fib 100000) then evaluating the entire buffer will take too long. Instead, do all your testing in the `*scheme*' buffer. To preserve your tests, you can write them out as a separate file. Once you have fully tested a procedure, you should save the transcript of your successful test cases into a separate buffer and write it to disk. At the end of the problem set, you can collect all of these transcripts into a single buffer and then print it out all at once.

**REPL Mode**

REPL is the major mode for communicating with an inferior read-eval-print loop (the `*scheme*' buffer is normally in the REPL major mode). All the editing and evaluation commands from Scheme mode are available in addition to the ones listed below.

C-c C-c  
    Stops an evaluation and returns to the top level. Can also be used like `Q' when Edwin displays ;Type D to debug error, Q to quit back to REP loop.

Expressions submitted for evaluation are saved in an expression history. The history may be accessed with the following commands:

M-p  
    Cycle backward through the history.

M-n  
    Cycle forward through the history.

C-c C-r  
    Search backward for a matching string.

C-c C-s  
    Search forward for a matching string.
M-p is the most frequently used history command. Imagine that you have typed \((+ 2 5)\) and then M-z. Now you wish to evaluate the same expression using a zero instead of the five. Typing M-p will recall the previous expression and place it into the current buffer where the point is located. Now you can use the normal editing commands to change the expression into the desired form. When you are done, you can type M-z to evaluate your new expression. At this point, typing M-p twice would recall the first expression, \((+ 2 5)\), while typing M-p just once would recall just the most recent expression, \((+ 2 0)\).

**Editing Commands**

This chapter documents the special features that Edwin shares with Emacs that allow you to edit Scheme code efficiently. These commands are almost always available in any major mode meant for editing.

**Lists and S-expressions**

By convention, Edwin keys for dealing with balanced expressions are usually Control-Meta characters. They tend to be analogous in function to the corresponding Control- and Meta- commands.

These commands fall into two classes. Some deal only with **lists** (parenthetical groupings). They see nothing except parentheses, brackets, braces, and escape characters that might be used to quote those.

The other commands deal with expressions or **s-expressions**. The word `s-expression' is derived from **symbolic expression**, the ancient term for any kind of expression in LISP. S-expressions are symbols, numbers, string constants, and lists.

C-M-a
Move to the beginning of the current definition (beginning-of-defun).

C-M-e
Move to the end of the current definition (end-of-defun).

C-M-f
Move forward over an expression (forward-sexp).

C-M-b
Move backward over an expression (backward-sexp).

C-M-k
Kill expression forward (kill-sexp).

C-M-u
Move up and backward in list structure (backward-up-list).

C-M-d
Move down and forward in list structure (down-list).
Don't Panic

C-M-n
   Move forward over a list (forward-list).
C-M-p
   Move backward over a list (backward-list).
C-M-t
   Transpose expressions (transpose-sexps).
C-M-SPC
   Put mark after following expression (mark-sexp).

These commands can be used to find an unbalanced parenthesis quite easily. To find an extra close parenthesis, move to the the beginning of the buffer and type an open parenthesis. Then move backwards one character and type C-M-f. The point should move to the definition with the extra parenthesis.

**Indentation**

TAB
   Indent current line "appropriately" for the current mode.
C-j
   Perform RET followed by TAB (newline-and-indent).
M-^[^1]
   Join current line with line above (delete-indentation). This cancels out the effect of LFD.
C-M-o
   Split line at point; text on the line after point becomes a new line indented to the same column that it now starts in (split-line).
M-m
   Move (forward or back) to the first non-blank character on the current line (back-to-indentation).
C-M-
   Indent several lines to same column (indent-region).
C-x TAB
   Shift block of lines rigidly right or left (indent-rigidly).
M-x indent-relative
   Indent from point to under an indentation point in the previous line.

In a Scheme mode buffer, lines are indented according to their nesting in parentheses. To indent a line, press TAB. In Scheme or REPL mode, TAB aligns the line according to its depth in parentheses. No matter where in the line you are when you type TAB, it aligns the line as a whole.

**Indenting Several Lines**

There are several commands that will re-indent several lines of code.
C-M-q
    Re-indent all the lines within one expression (indent-sexp).

C-u TAB
    Shift an entire expression rigidly sideways so that its first line is properly indented.

C-M-\n    Re-indent all lines in the region (indent-region).

You can re-indent the contents of a single expression by positioning the point before the beginning of it and typing C-M-q (indent-sexp). The indentation of the current line is not changed; therefore, only the relative indentation within the list, and not its position, is changed. To correct the position as well, type a TAB before the C-M-q.

C-M-q is a great way to indent the current definition. Move to the beginning of the current definition using C-M-a before you use this command.

If the relative indentation within an expression is correct but the indentation of its beginning is not, go to the line the expression begins on and type C-u TAB. When TAB is given a numeric argument, it moves all the lines in the grouping starting on the current line sideways the same amount that the current line moves. It is clever, though, and does not move lines that start inside strings.

Another way to specify the range to be re-indented is with the point and mark. The command C-M-\ (indent-region) applies TAB to every line whose first character is between the point and mark.

Completion for Scheme Symbols

Completion maximizes the entropy of your keystrokes. Whenever the computer can figure out what you mean to type, you may tell it to type the rest for you. Usually completion happens in the mini-buffer. But one kind of completion is available in Scheme and REPL buffers: completion for Scheme symbol names.

The command M-TAB takes the partial Scheme variable name before point to be an abbreviation, and compares it against all bound variables in the REPL environment. Any additional characters that they all have in common are inserted at the point.

If the partial name in the buffer is not a unique prefix, a list of all possible completions is displayed in another window. At this point you can type enough characters to make the symbol unique and press M-TAB again.

C-u M-TAB works like M-TAB except that it also completes symbols.
Debugger

When an error occurs in your code, you will be asked whether you would like to enter the debugger. The debugger creates two buffers in which debugging information is presented. The contents of the buffers will change based on the commands you enter.

```
left-mouse-button
    Select a subproblem or reduction and display information in the description buffer.
C-n
don-down-arrow
    Move the cursor down the list of subproblems and reductions and display info in the description buffer.
C-p
up-arrow
    Move the cursor up the list of subproblems and reductions and display info in the description buffer.
e
    Show the environment structure.
q
    Quit the debugger, destroying its window.
p
    Invoke the standard restarts.
?SPC
    Display info on current item in the description buffer.
?                      Display help information.
```

Each line beginning with `S' represents either a subproblem or a stack frame. A subproblem line may be followed by one or more indented lines (beginning with the letter `R') which represent reductions associated with that subproblem. To obtain a more complete description of a subproblem or reduction, click the mouse on the desired line or move the cursor to the line using the arrow keys (or C-n and C-p). The description buffer will display the additional information.

The description buffer contains three major regions which contain information associated with the selected subproblem or reduction. The first region contains a pretty printed version of the expression. The second region contains a representation of the environment. The variables in the frames are listed along with there values. The bottom of the description buffer contains a region for evaluating expressions in the environment of the selected subproblem or reduction (similar to the `*scheme*' buffer). This is the only portion of the buffer where editing is possible. Evaluating expressions here can be useful in gathering information about the circumstances of the bug.

Typing e creates a new buffer in which you may browse through the current environment. In this new
buffer, you can use the mouse, the arrows, or C-n and C-p to select lines and view different environments. The environments listed are the same as those in the description buffer. If the selected environment structure is too large to display (if there are more than environment-package-limit items in the environment) an appropriate message is displayed. To display the environment in this case, set the environment-package-limit variable to #f. This process is initiated by the command M-x set-variable. You can not use set! to set the variable because it is an editor variable and does not exist in the current scheme environment. At the bottom of the new buffer is a region for evaluating expressions similar to that of the description buffer.

Type q or to quit the debugger, killing its primary buffer and any others that it has created.

NOTE: The debugger creates description buffers in which debugging information is presented. These buffers are given names beginning with spaces so that they do not appear in the buffer list; they are automatically deleted when you quit the debugger using q. If you wish to keep one of these buffers, rename it using M-x rename-buffer: once it has been renamed, it will not be deleted automatically.

**Subproblems and Reductions**

Understanding the concepts of **reduction** and **subproblem** is essential to good use of the debugging tools. The Scheme interpreter evaluates an expression by **reducing** it to a simpler expression. In general, Scheme's evaluation rules designate that evaluation proceeds from one expression to the next by either starting to work on a **subexpression** of the given expression, or by **reducing** the entire expression to a new (simpler, or reduced) form. Thus, a history of the successive forms processed during the evaluation of an expression will show a sequence of subproblems, where each subproblem may consist of a sequence of reductions.

For example, both (+ 5 6) and (+ 7 9) are subproblems of the following combination:

\[
(*) (+ 5 6) (+ 7 9)
\]

If (prime? n) is true, then (cons 'prime n) is the reduction for the following expression:

\[
(if (prime? n)
  (cons 'prime n)
  (cons 'not-prime n))
\]

This is because the entire subproblem of the if combination can be **reduced** to the problem (cons 'prime n), once we know that (prime? n) is true; the (cons 'not-prime n) can be ignored, because it will never be needed. On the other hand, if (prime? n) were false, then (cons 'not-prime n) would be the reduction for the if combination.
The **subproblem level** is a number representing how far back in the history of the current computation a particular evaluation is. Consider **factorial**:

```scheme
(define (factorial n)
  (if (< n 2)
    1
    (* n (factorial (- n 1)))))
```

If we stop **factorial** in the middle of evaluating `(- n 1)`, the `(- n 1)` is at subproblem level 0. Following the history of the computation "upwards," `(factorial (- n 1))` is at subproblem level 1, and `(* n (factorial (- n 1)))` is at subproblem level 2. These expressions all have **reduction number** 0. Continuing upwards, the **if** combination has reduction number 1.

Moving backwards in the history of a computation, subproblem levels and reduction numbers increase, starting from zero at the expression currently being evaluated. Reduction numbers increase until the next subproblem, where they start over at zero. The best way to get a feel for subproblem levels and reduction numbers is to experiment with the debugger.

## Glossary

**Buffer**

A **buffer** is a block of text that you may examine and change. Whenever you edit in Edwin, you change the contents of a buffer. To preserve a buffer for another time you will use Edwin, you must **save** the buffer to a **file** on disk. Then you must remember to checkpoint your floppy disk.

**Commands**

A **command** is an instruction you give Edwin through a special key combination. For example, use the `C-x C-f` command to copy a file from a disk into a new buffer.

**Cursor**

The cursor is a solid rectangle visible on the screen whenever the computer is waiting for you to type something. If you type an ordinary character (letter, number, or punctuation), it will be inserted at the current cursor position, and the cursor will move past it.

**Extended Commands**

An **extended command** is a command used by name, rather than by a special key. To use an extended command, press `M-x`, followed by the name of the command. Your typing will appear at the bottom of the screen, in the mini-buffer (see below). When you've typed the full name of the extended command, press `RET`.

**File**

A **file** is a block of text stored on a disk. A file may be copied from a disk into a buffer. A file is created by saving the contents of a buffer on a disk.

**Kills**

The several most recently-deleted regions are kept in the **kill ring**. Killed text can be retrieved with a **yank**.
Mark

The **mark** is an invisible point in a buffer. Many commands set it to the buffer location where they were performed. Each buffer has its own mark. `C-x C-x` exchanges the point and the mark, thus revealing the mark.

Mini-buffer

The **mini-buffer** is that last line of the Edwin window. It is used by Edwin to display informative messages and to prompt you for various inputs, for example, file names, confirmation, etc.

Modes

Every buffer has one major mode, and maybe some minor modes. **Major modes** determine special Edwin behavior particular to the language you are using (e.g., Scheme or English). **Minor modes** add special features regardless of the language you are using in the buffer.

Point

The current cursor location in each buffer is called the **point**. The cursor is just a reflection of the point in the current buffer.

Region

Text between the **point** and the **mark** is called the **region**.

Saving

To **save** is to create a disk file from a buffer. The file and the buffer are identical, but only the file remains when you log out; the buffer is erased. However if you don't checkpoint your files onto your floppy disk, your files will be erased when someone else logs into the machine.

Window

A **window** has two meanings. When referring just to Edwin, it is a rectangular area on the screen sometimes called a **text window**. When referring to a program in general, it is an area of the screen that contains text or graphics and is manipulated by the window manager. Each text window displays part of some buffer. Because most buffers are too big to fit in one window, only part of the buffer is visible at any time; you can see other parts by using Edwin commands to scroll through the buffer.
