Chapter 11
Bon voyage!

The theme of this book is how to understand new fields, whether the field is known generally but is new to you; or the field is new to everyone. In either case, certain ways of thinking promote understanding and long-term learning. This afterword illustrates these ways by using an example that has appeared twice in the book – the volume of a pyramid.

11.1 Remember nothing!

The volume is proportional to the height, because of the drilling-core argument. So \( V \propto h \).

But a dimensionally correct expression for the volume needs two additional lengths. They can come only from \( b^2 \). So

\[
V \sim bh^2.
\]

But what is the constant? It turns out to be 1/3.

11.2 Connect to other problems

Is that 3 in the denominator new information to remember? No! That piece of information also connects to other problems.

First, you can derive it by using special cases, which is the subject of Section 8.1.

Second, 3 is also the dimensionality of space. That fact is not a coincidence. Consider the simpler but analogous problem of the area of a triangle. Its area is

\[
A = \frac{1}{2}bh.
\]

The area has a similar form as the volume of the pyramid: A constant times a factor related to the base times the height. In two dimensions the constant is 1/2. So the 1/3 is likely to arise from the dimensionality of space.

That analysis makes the 3 easy to remember and thereby the whole formula for the volume.

But there are two follow-up questions. The first is: Why does the dimensionality of space matter? The special-cases argument explains it because you need pyramids for each direction of space (I say no more for the moment until we do the special-cases argument in lecture!).
The second follow-up question is: Does the 3 occur in other problems and for the same reason? A related place is the volume of a sphere

\[ V = \frac{4}{3} \pi r^3. \]

The ancient Greeks showed that the 3 in the $4/3$ is the same 3 as in the pyramid volume. To explain their picture, I’ll use method to find the area of a circle then use it to find the volume of a sphere.

Divide a circle into many pie wedges. To find its area, cut somewhere on the circumference and unroll it into this shape:

![Circle unrolled into triangles](image)

Each pie wedge is almost a triangle, so its area is $bh/2$, where the height $h$ is approximately $r$. The sum of all the bases is the circumference $2\pi r$, so $A = 2\pi r \times r/2 = \pi r^2$.

Now do the same procedure with a sphere: Divide it into small pieces that are almost pyramids, then unfold it. The unfolded sphere has a base area of $4\pi r^2$, which is the surface area of the sphere. So the volume of all the mini pyramids is

\[ V = \frac{1}{3} \times \text{height} \times \text{basearea} = \frac{4}{3} \pi r^3. \]

Voilà! So, if you remember the volume of a sphere – and most of us have had it etched into our minds during our schooling – then you know that the volume of a pyramid contains a factor of 3 in the denominator.

### 11.3 Percolation model

The moral of the preceding examples is to build connections. A physical illustration of this process is percolation. Imagine how oil diffuses through rock. The rock has pores through which oil moves from zone to zone. However, many pores are blocked by mineral deposits. How does the oil percolate through that kind of rock?
