Glides

Figure 9.19 Mid sagittal sections when the vocal tract reaches its most constricted configuration for the glides /w/ (left) and /j/ (right). In the case of /w/, the frontal lip contour is also shown, to illustrate the lip rounding. (Adapted from Bothorel et al., 1986)

Figure 9.34 Spectrograms of the utterances /a y:kt/ and /a w:lt/ produced by a female speaker (top) and a male speaker (bottom). Measured F1 trajectories are superimposed on the spectrograms.
Figure 9.33 Same as figure 9.27, except that the utterance is /s/old/. The female speaker is represented in the left panels and the male speaker in the right panels.

Figure 3.15 Uniform tube with a narrow constriction used to approximate area functions for consonants.
Figure 9.1: Midsagittal sections through the vocal tract during the production of nasal consonants produced by closing the lips (left) and raising the tongue tip to the alveolar ridge (right). For the labial consonant, the context is "Mets tes braus habla," and for the alveolar consonant the context is "Une réponse ..." (Adapted from Bothorel et al., 1986.)

Figure 9.2: Schematization of the time course of the cross-sectional area of the oral constriction (upper panel) and of the velopharyngeal opening (lower panel) during production of a nasal consonant in intervocalic position. The detailed shapes of these trajectories depend on the place of articulation for the consonant and for the adjacent sounds.

Figure 3.16 Relations between natural frequencies and the position of the constriction for the configuration shown in figure 3.15. The overall length of the tube is 10 cm and the length of the constriction is 2 cm. The lines sloping up to the right represent the resonances of the front cavity (anterior to the constriction); the lines sloping down to the right represent the resonances of the back cavity. The solid lines are the resonances if there is no coupling between front and back cavities. The dashed lines near the point of coincidence of two resonances at $l_1 = 9.3$ cm illustrate the shift in the resonant frequencies for the case where there is a small amount of coupling between front and back cavities. When the area of the constriction is very small, $F_1 = 0$ as shown. When the constriction is larger, $F_1$ increases as shown by the dashed line. The resonances of a 10-cm tube with no constriction are shown by the labeled marks at the right. The curves are labeled with the appropriate formant numbers.

Figure 7.17 Schematic representation of sequence of events at the release of a voiceless unaspirated stop consonant. (From K. N. Stevens 1998b)

Figure 7.18 Acoustic data obtained from an utterance of a voiceless unaspirated stop consonant /p/ in the intervocalic environment /op/ (the same utterance as that displayed in figure 7.12a) A spectrogram of the utterance is shown at the top, and spectra and waveforms at the burst and 10 ms later are given below. The spectra are discrete Fourier transforms calculated with a Hamming window of 6.4 ms duration.

Figure 8.71a and b  Samples of acoustic data for two voiced stop consonants in intervocalic position. The utterances are a *b* (a) and a *d* (b). The spectrogram of the utterance is displayed at the top. In the center below the spectrogram are plots of the time course of several parameters: the amplitude of the first harmonic, obtained from a discrete Fourier transform at 10-ms intervals; the frequencies of the first and second formants measured from the peaks in a 64-ms discrete Fourier transform centered on the initial part of each glottal period, with interpolations in the closure interval shown as dashed lines; and the fundamental frequency. The vertical lines indicate the instants of consonant closure and release, as estimated from the acoustic signal. The spectra at the left and right are sampled at times near the implosion and release respectively; they are discrete Fourier transforms with a 64-ms Hamming window. The waveform and the time window are shown below each spectrum.

Figure 9.1 Midsagittal sections obtained from cineradiographs during the production of the three fricative consonants /f/, /s/, and /z/, as indicated. The subject is an adult female speaker of French. The approximate scale is given between the /f/ and /s/ configurations. In the case of the /s/ configuration, an estimate of the cross-sectional shape at the constriction is given. (This shape is drawn with an enlarged scale, as shown.) For each panel, two midsagittal sections for the tongue (and, in the case of /z/, for the lips) are shown, representing the fricative in two different phonetic environments. For /f/, the following vowel contexts are the high front rounded vowel /i/ (solid line) and /y/ (dashed line); for /s/, /a/ (solid line) and /i/ (dashed line); and for /z/, /a/ (solid line) and /a/ (dashed line). (After Bothorel et al., 1986.)

Figure 8.76  Samples of acoustic data for the intervocalic voiced fricative consonant /h/ in the utterance a zip. The spectrogram of the utterance is shown at the top left; and below this are: $H_1$, the amplitude of the first harmonic, measured as in figure 8.71; "noise," the amplitude of the fricative noise, taken to be the peak spectrum amplitude (64-ms window) in the frequency range of 3.5 to 5 kHz; $F_1$, the first formant frequency, measured as in figure 8.71; the difference $H_1 - H_2$ between the amplitudes (in decibels) of the first and second harmonics; and $F_0$, the fundamental frequency. The vertical lines are estimates of the points where intracord pressure begins to build up and where the pressure begins to decrease, based on examination of the acoustic record. Spectra at selected points near the left and right boundaries of the fricative are displayed at the right, together with waveforms and time windows (64-ms duration). The noise spectrum (panel 4) was obtained by averaging spectra over a 35-ms time interval. All other spectra were calculated with a single time window.
