Phony Programming
(Series 60 Symbian Phones)

Larry Rudolph
MIT 6.883 & SMA 5508
March 6, 2006
What’s so special about phones?

• Ignorant Operator
  • really ignorant operator

• Scarce Resources
  • Power -- slow processor, small memory, small disk
  • Size -- Screen and keyboard area
  • Heat -- To keep this low, must constrain above
  • Price -- Different than PC, since each feature costs the same, due to volumes
  • Reboot -- these are rare events
  • Brand loyalty -- hardly any, mistakes are costly

• It’s new and exciting!
What’s so special about phony programming?

• Inherently very little --- Practically very much
• History
  • originally: phones were h/w appliances
  • past: s/w - h/w co-design reduced costs
  • near past: new features all s/w
  • near future: 3rd party software
• In computer world, two approaches
  • Intel: H/W, Microsoft: O/S, separate h/w from s/w
  • Apple: H/W & S/W, easier to integrate, high costs $
• Companies have no history of being open !!
Current Choices

• Most phones have two ASICs
  • Modem/Telephone service
  • Embedded processor and extra features
• Palm-Based: Slow to integrate
• Pocket-PC: Appears to be aggressive
  • Can they maintain two OS’s (Windows & WinCE)?
• Linux: (actually, Linux+Java)
  • Still hidden from user Motorola phones
  • iPaq 6315 has GSM/SIM
• Symbian: Mostly on Nokia and Sony/Ericsson
• IDC Predicts: Pa:10%, Po:27%, Li:4%, Sy:53%
Palm Phones
Pocket PC Phones
Linux Based Phones
Symbian Phones
Symbian Epoc OS

- Originally developed for the Psion handheld computer
  - competition with Palm
  - single user, small memory, instant-on, no network
- EPOC operating system
- Symbian independent company
  - partly owned by Nokia, Sony (no one controls them)
  - EPOC and Symbian names became intermixed
- Nearly all documentation and tools are for commercial developers
  - high start-up cost
Larry’s Deja Vu

• Despite the fact that
  • Programmable Mobile Phones are new artifacts
  • the OS and programming repeat mistakes
• Designs that make sense for disconnected, single use devices, remain as devices become connected and multi-use and multi-tasked.
  • Inertia is a powerful force
Programming Languages
Series 60 Phones

• C++ for Symbian
  • access to all the phones functions
  • not so easy

• Java
  • highly sandboxed.
  • no access to file system, phone, and more
  • not the choice language for virus writers

• Python
  • nearly ready for public release
  • will have interface to all Symbian API’s
Symbian OS Basics

• Kernel: Protected Mode; Controls H/W

• Server: Manages one or more resources
  • no UI (user interface)
  • yes API (application program interface)
  • may be device driver or kernel service

• Application: A program with a UI
  • Each application is a process; own virtual address
  • If interacts with server, can be called a client

• Engine: part of app. manipulates its data not UI
Processes & Threads

• Three boundaries
  • DLL or module: cheap to cross
  • Privilege: medium to cross
  • Process: expensive to cross

• Processes, Threads, Context Switches
  • Process: has its own address space (256 MB)
  • Thread: Unit of execution within a process
    • Preemptively scheduled; 2MB nonshared ==> 128 thds/pro

• Executables
  • exe: single entry point
  • dynamic link library (DLL): multiple entries
    • Shared (OS) vs Polymorphic (app)
RAM Memory Parts

Figure by MIT OCW.
Memory

• **RAM**: partitioned into 4k pages
  - kernel, process, DLL, MMU tables, Video, C:
  - Thread memory: Shared:Heap, Nonshared:Stack
• **DLL**: no writable static data (yes for exe’s)
  - requires multiple copies of instantiated dll
• **Files** (does this remind you of something)
  - C: RAM -- r/w file system. Zero’d on cold boot
    - restored from ROM on cold boot
  - Z: ROM -- can be reflashed (not easy)
  - D: Memory Card
    - 512 byte blocks written atomically; VFAT format
Event Handling

• Efficient handling major OS design
  • native OS server is single event-handling thread

• Symbian organized as Event-driven

• Active Objects: non-preemptive event handling
  • and client-server structure
Response to key-press

Keyboard → ISR/DFC → Interrupt
ISR/DFC → Kernel/Driver
Kernel/Driver → Window Server
Window Server → Application
Application → CPU Power

Update Window → Draw Request
Draw Request → Handle Key Event
Handle Key Event → Key Event
Key Event → Handle Key Event
Handle Key Event → Update Window
Active Objects

• Each active object has virtual member function called RunL()
  • gets called when event happens
  • events have associated priority

• Active Objects execute non-preemptively
  • RunL() should execute for short time
  • no need for mutex, semaphores, critical sections
  • fewer context-switches

• Compute-intensive threads:
  • Simulate using pseudoevents
  • split task into pieces, generate low-prio event
Server
Inter-thread read
Inter-thread write
Response
Request
Client Interface
Client
Kernel Executive
User Privilege
Kernel Privilege

Figure by MIT OCW.
Java Programming

• Lots of examples at www.forum.nokia.com
  • great for games and network connectivity
• Compile on server
• Install on phone via:
  • bluetooth connection
  • mms message (email)
  • upload from web server
• On phone, java applet must be opened to install before being run.
C++ Programming

• The real stuff but documentation is difficult

• Everything depends on the SDK
  • Software Development Kit runs under Windows
  • The processor on phone is ARM (same as iPaq)
  • Must do cross-compilation
    • compile with different libraries and assembly instructions
  • There is an “Emulator” -- but it is really a simulator
    • e.g. it executes x86 code not arm code
    • so must compile either for ARM or x86
    • emulator is needed for debugging

Pervasive Computing MIT 6.883 SMA 5508 Spring 2006 Larry Rudolph
C++ Programming

• Tutorials: C++ for Java programmers
  • There are many others on-line
  • Easier to go from java to c++ (java has less weirdness)
## Symbian Layers

<table>
<thead>
<tr>
<th>Group</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Base</td>
<td>Provides the fundamental APIs for all of Symbian OS, which I've described in this chapter.</td>
</tr>
<tr>
<td>Middleware</td>
<td>Graphics, data, and other components to support the GUI, engines, and applications.</td>
</tr>
<tr>
<td>UI</td>
<td>The system GUI framework including the Shell (in UIQ, the Application Launcher) application.</td>
</tr>
</tbody>
</table>

Figure by MIT OCW.
<table>
<thead>
<tr>
<th>Applications</th>
<th>Applications software can be divided into GUI parts (which use UIQ) and engines (which don't deal with graphics). Some applications are simply thin layers over middleware components: others have substantial engines.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Communications</td>
<td>Industry-standard communications protocols for serial and sockets-based communication, dial-up networking TCP/IP, and infrared.</td>
</tr>
<tr>
<td>Language systems</td>
<td>The Java runtime environment.</td>
</tr>
<tr>
<td>Symbian OS Connect</td>
<td>Communications protocols to connect to a PC, and services such as file format conversion, data synchronization for contacts, schedule entries and e-mail, clipboard synchronization, printing to a PC-based printer.</td>
</tr>
</tbody>
</table>
Symbian 60 Phone Programming in Python

March 2006
Installing stuff

• a package or installation file in symbian:
  • application_name.sis

• Get it onto the phone
  • push via bluetooth (or send message)

• Open up message and install
  • if there is flash memory, install it there
import appuifw

appuifw.note(u'Hello World', u'info')

import appuifw  # the application user interface fw(?)
u’Hello World’,  # u’ ‘ for a unicode string. All GUI
                # strings are unicode. Others can be
u’info’        # specifies the type of note
Get User Input

```
import appuifw
planet = appuifw.query(u'Which planet?', u'text')
appuifw.note(u'Hello ' + planet, u'info')
```

“query()” pops up a dialog with prompt string and input type
other types can be ‘number’ ‘date’ ‘code’
the ‘+’ concatenates the two unicode strings
Get More User Input

import appuifw
planets = [ u’Mars’, u’Earth’, u’Venus’ ]
prompt = u’Enter your home planet’
index = appuifw.menu(planets, prompt)
appuifw.note(u’Hello ’+planets[index] , u’info’)

The ‘menu’ method pops up the list of items in first param
It returns with an index into the list of menu items
Note that the prompt param must also be a unicode string
Our own interface:

sma.py

There are a bunch of annoyances in the current UI

Let’s put wrappers around basic calls

We should go back and do this for location
# this is file sma.py
# wrappers to appuifw, e32, and bluetooth

def note( str , type = 'info'):  
    appuifw.note( unicode(str), type )

def query( str , type = 'text' ):  
    return appuifw.query( unicode(str), type )

def menu( list, prompt = 'select one' ):  
    ulist = [ unicode(u) : for u in list ]  
    return appuifw.menu( ulist , unicode( prompt ) )
import sma

planets = [ 'Mars', 'Earth', 'Venus' ]
prompt = 'Enter your home planet'
index = sma.menu(planets, prompt)
sma.note('Hello ' + planets[index] )
No more slides

• It is easier to go through the python reference document, rather than reproducing it all here...
