

# Introduction to Engineering Systems, ESD.00

## Networks

Lecture 7

Lecturers:

Professor Joseph Sussman

Dr. Afreen Siddiqi

TA: Regina Clewlow

Massachusetts Institute of Technology  
**Engineering Systems Division**

# The Bridges of Königsberg

- The town of Königsberg in 18<sup>th</sup> century Prussia included two islands and seven bridges over the river Pregel.
- Residents had often thought about finding a walk such that starting from any of the four places, A,B,C,D, one crosses all of the seven bridges only once and then returns to the starting place.
- No one could find such a walk....

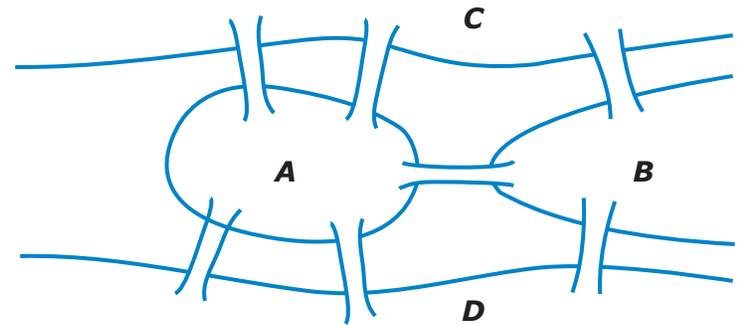

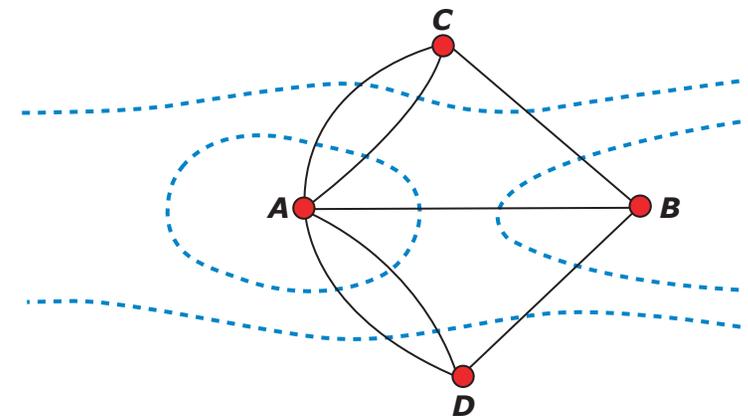

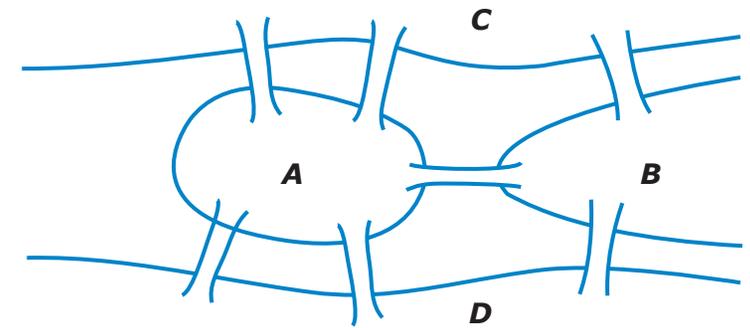

Image by MIT OpenCourseWare.

Figure: <http://www.transtutors.com/homework-help/Discrete+Mathematics/Graph+Theory/konisberg-multigraph-bridge.aspx>

# Graph Theory

- Leonhard Euler, in 1736, came up with the realization that this was not a problem of traditional geometry – measurements of angles, lengths, orientations do not matter.
- **The only two things that mattered were whether the islands or banks are connected by a bridge, and by how many bridges.**
- He modeled each place (island or bank) as a ‘vertex’ and each bridge as an ‘edge’ that connected the vertices.
- He mathematically proved that no such walk existed for the Königsberg problem and founded an entirely new branch of mathematics along the way.

Images by MIT OpenCourseWare.

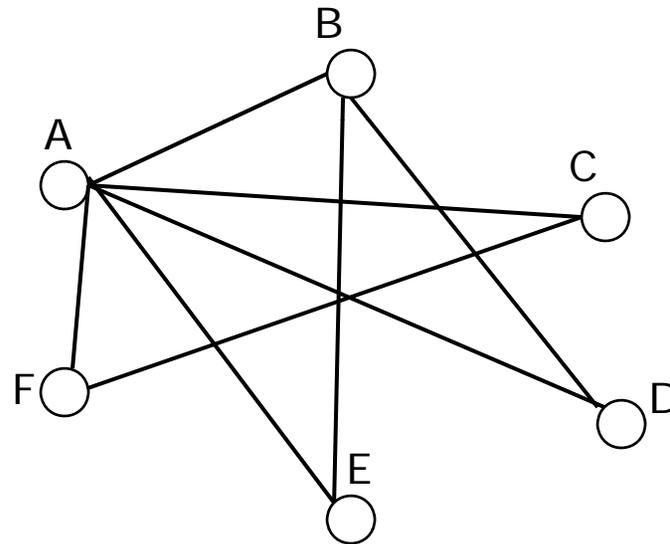

# Modeling Example - I

There were six people: A, B, C, D, E, and F in a party and following handshakes among them took place:

A shook hands with B, C, D, E and F

B, in addition, shook hands with D and E

C, in addition, shook hands with F

Ref [3]

# Modeling Example - II

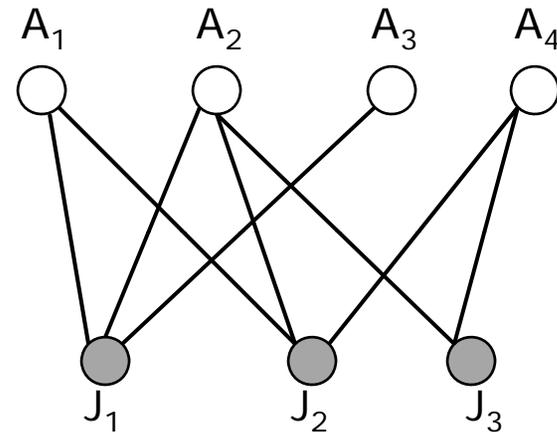

Consider a job application problem. There are three jobs  $J_1, J_2, J_3$  for which four applicants  $A_1, A_2, A_3, A_4$  have applied.

$A_1$  has applied for  $J_1$  and  $J_2$

$A_2$  has applied for  $J_1, J_2$  and  $J_3$

$A_3$  has applied for  $J_1$

$A_4$  has applied for  $J_2$  and  $J_3$

This type of graph is called a **bi-partite graph**.

A bi-partite graph has two types of vertices (nodes) and there are no edges between nodes of the same type.

Ref [3]

# Modeling Example - III

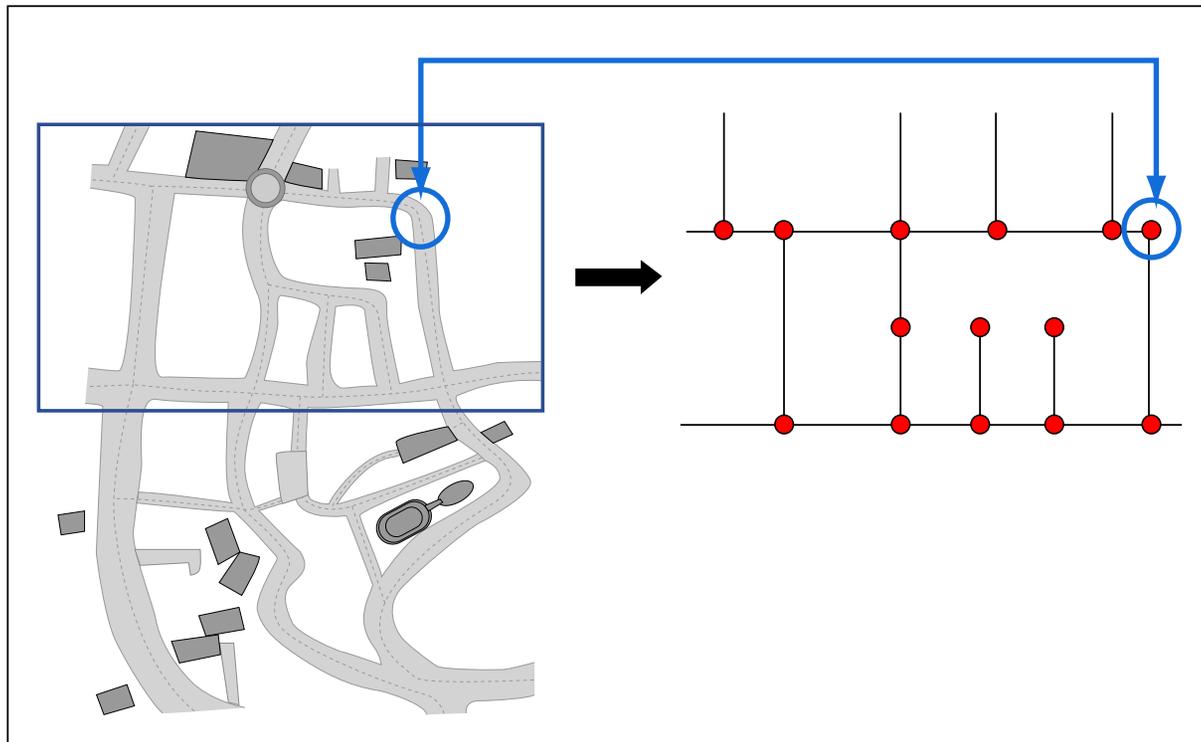

Image by MIT OpenCourseWare.

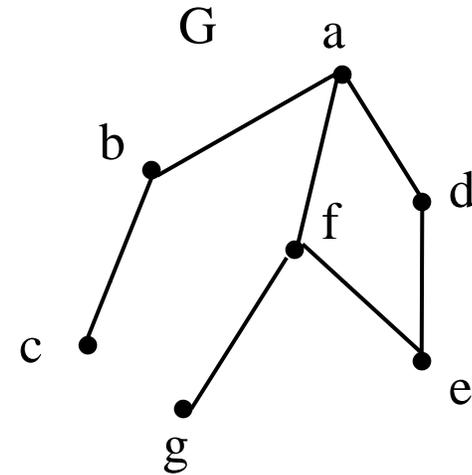

<http://cvpr.uni-muenster.de/teaching/ws10/projektseminarWS10/>

[http://www.airlineroutemaps.com/USA/American\\_Airlines\\_caribbean.shtml](http://www.airlineroutemaps.com/USA/American_Airlines_caribbean.shtml)

# Graphs

Ref [3]

- A graph is a finite collection of vertices (or nodes) and edges (or links).
- To indicate a graph  $G$  has vertex set  $V$  and edge set  $E$ , we write  $G=(V,E)$
- Each edge  $\{x,y\}$  of  $G$  is usually denoted by  $xy$ , or  $yx$ .
- What is the vertex set  $V(G)$  and edge set  $E(G)$  of the graph  $G$  shown?

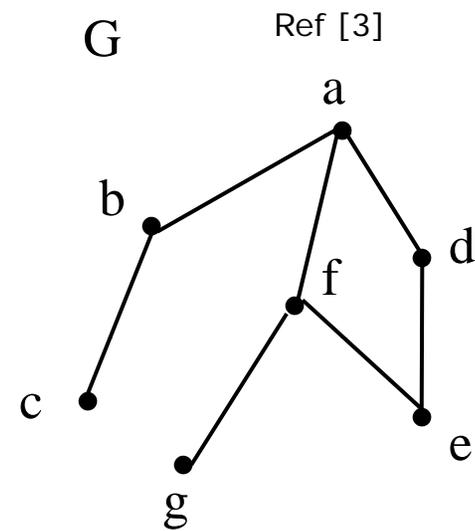

$$V(G)=\{a, b, c, d, e, f, g\}$$

$$E(G)=\{ab, bc, ad, de, af, fg, fe\}$$

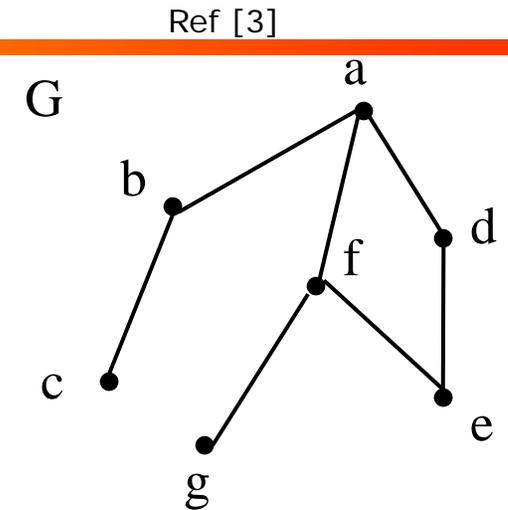

# Adjacency

- If  $xy$  is an edge of  $G$ , the  $x$  and  $y$  are **adjacent vertices**
- Two adjacent vertices are referred to as **neighbors** of each other
- The set of neighbors of a vertex  $v$  is called the **open neighborhood** (or simply neighborhood) of  $v$  and is denoted as  $N(v)$
- For graph  $G$  shown on the right, what is:
  - $N(a)$  ?
  - $N(f)$  ?
  - $N(b)$  ?

# Order and Size

- The **number of vertices** in a graph  $G$  is the **order** of  $G$
- The **number of edges** in  $G$  is the **size** of  $G$
- The order of  $G$  (as shown on the right) is \_\_\_
- The size of  $G$  (as shown on the right) is \_\_\_
- A graph of size 0 is called an empty graph – no two vertices are adjacent.
- A graph in which every pair of two vertices are adjacent is called a **complete graph**

# Multi-Graphs

- So far we've considered only zero or one edge between a pair of vertices
- What if there are more edges?
- Consider Euler's graph for the Königsberg problem
- The graph  $K$  is a **multigraph**
- A multigraph has finite number of edges (including zero) between any two vertices
- So all graphs are multigraphs but not vice versa
- No loops are allowed in a multigraph – a vertex cannot connect to itself

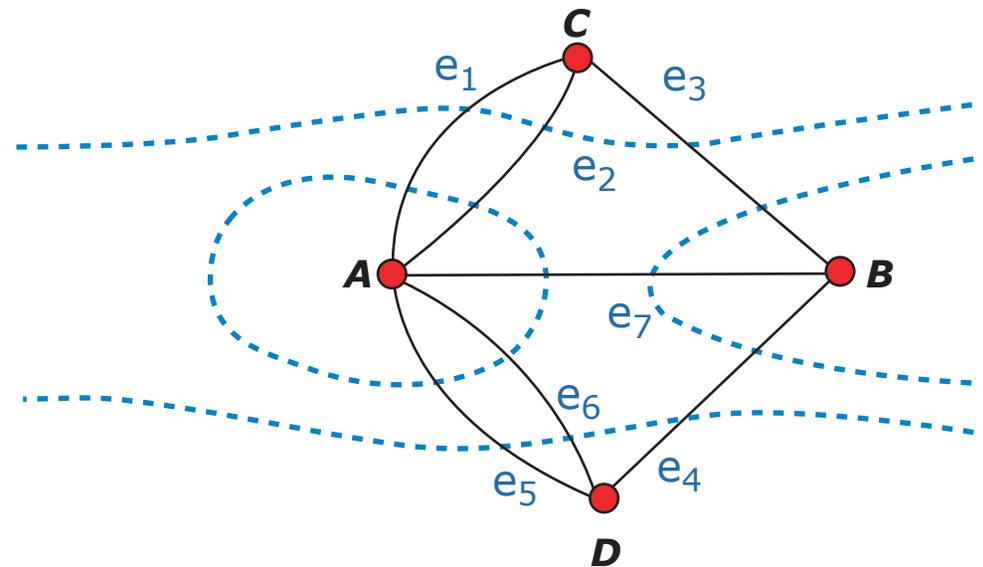

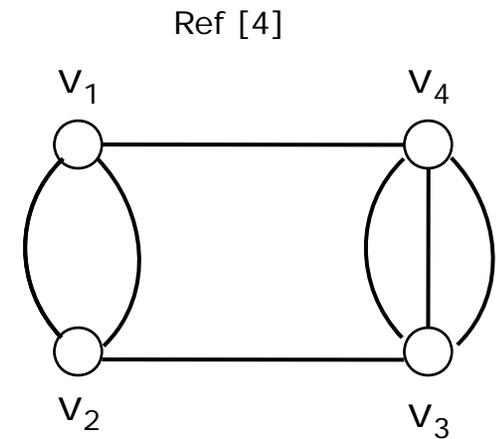

Image by MIT OpenCourseWare.

# Adjacency Matrix

- In addition to set representation, we can use matrices to represent multigraphs
- We can create an **adjacency matrix**  $A$  such that its each  $(i,j)$  entry is the number of edges that exist between vertex  $i$  and vertex  $j$
- For a multigraph  $G$  of order  $n$  with  $V(G)=\{v_1, v_2, v_3..v_n\}$ , the adjacency matrix of  $G$  is  $n \times n$ 
  - $A(G) = [a_{ij}]_{n \times n}$
  - where  $a_{ij}$ , the  $(i,j)$ -entry in  $A(G)$  is the number of edges joining  $v_i$  and  $v_j$

$$A = \begin{bmatrix} 0 & 2 & 0 & 1 \\ 2 & 0 & 1 & 0 \\ 0 & 1 & 0 & 3 \\ 1 & 0 & 3 & 0 \end{bmatrix}$$

↑  
there are three edges between  $v_3$  and  $v_4$

# Exercise

---

Draw  $G$  when  $G(A)$  is:

$$A = \begin{bmatrix} 0 & 1 & 0 & 2 & 3 \\ 1 & 0 & 1 & 2 & 2 \\ 0 & 1 & 0 & 1 & 1 \\ 2 & 2 & 1 & 0 & 1 \\ 3 & 2 & 1 & 1 & 0 \end{bmatrix}$$

Why are the elements of the diagonal always zero?

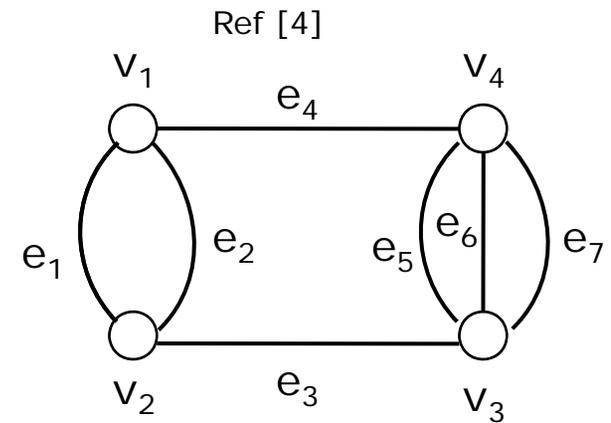

What is the order ( $n$ ) of  $G$ ?

What is the size ( $m$ ) of  $G$ ?

How can you determine  $m$  from  $A$ ?

# Incidence Matrix

- The Incidence Matrix,  $B$  is a binary,  $n \times m$  matrix, where  $b_{ij} = 1$  if  $v_i$  is an endvertex of edge  $e_j$ , otherwise it is zero.
- The incidence matrix contains more information than an adjacency matrix since it distinguishes between edges.
- Each column has two ones if each edge has two distinct vertices (i.e. when there are no loops and the graph is connected).

$$B = \begin{bmatrix} 1 & 1 & 0 & 1 & 0 & 0 & 0 \\ 1 & 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 \end{bmatrix}$$

$v_4$  is an endvertex of  $e_4, e_5, e_6,$  and  $e_7$

# Vertex Degrees

- Given a vertex  $v$  in  $G$ , the degree of  $v$  in  $G$ , denoted by  $d_G(v)$ , is defined as the number of edges incident with  $v$ .
- Which vertex has the highest degree in the Koningsberg problem? What is its degree?
- **In a multigraph, the sum of the degrees of its vertices is twice its size (number of edges).**

$$\sum_{i=1}^n d(v_i) = 2m$$

This is also known as the 'Hand-Shaking Theorem'

- A vertex with the highest degree is called a **hub** in a graph (or network).

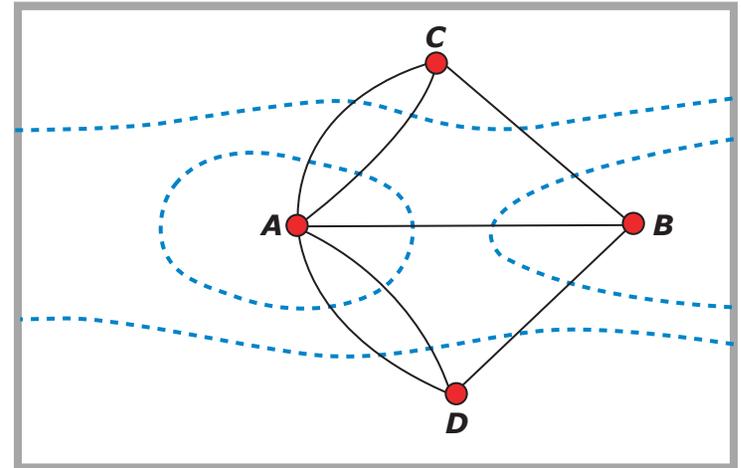

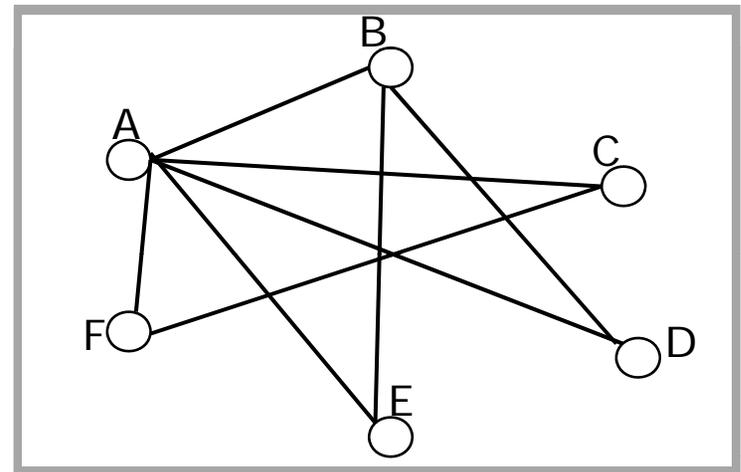

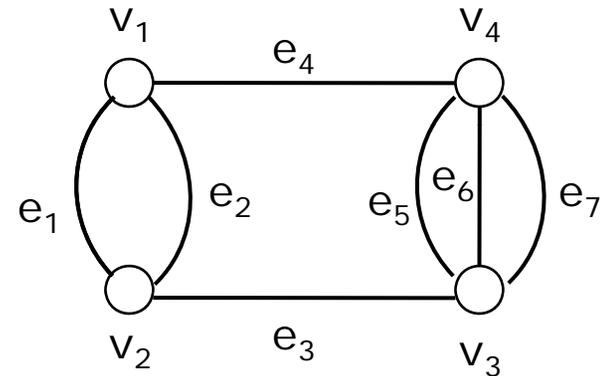

Image by MIT OpenCourseWare.

# Degrees from A and B

- Given an adjacency matrix,  $A$ , can we determine  $d(v_i)$  ?
- Can we determine  $d(v_i)$  from incidence matrix,  $B$ ?

$$A = \begin{bmatrix} 0 & 2 & 0 & 1 \\ 2 & 0 & 1 & 0 \\ 0 & 1 & 0 & 3 \\ 1 & 0 & 3 & 0 \end{bmatrix}$$

$$B = \begin{bmatrix} 1 & 1 & 0 & 1 & 0 & 0 & 0 \\ 1 & 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 \end{bmatrix}$$

# Complete Graphs

- What is the total number of edges,  $m$ , in a **complete graph**?
- For a graph of order  $n$  (i.e.  $n$  vertices), what is the number of total possible combinations if we pick two vertices at a time?
- Think *Combination* – out of  $n$  objects, how many combinations are possible if we pick  $k$  objects at a time?
- This is given by the Binomial coefficient:

$$\binom{n}{k} = \frac{n(n-1)\dots(n-k+1)}{k(k-1)\dots 1} = \frac{n!}{k!(n-k)!}$$

$k \leq n$

$$m = \binom{n}{2} = \frac{n!}{2!(n-2)!} = \frac{n(n-1)(n-2)!}{2!(n-2)!} = \boxed{\frac{n(n-1)}{2}}$$

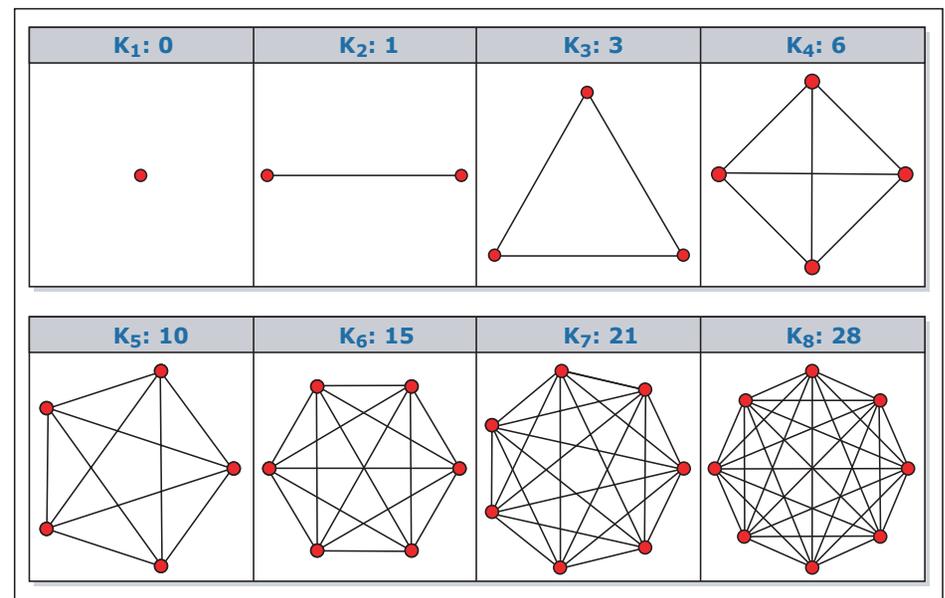

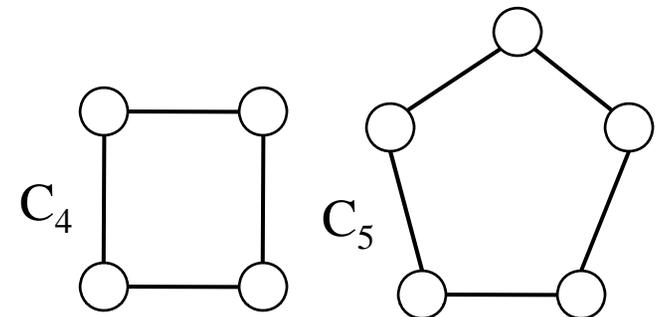

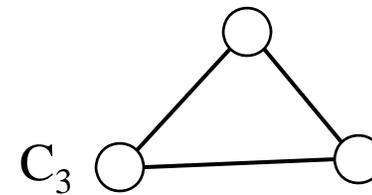

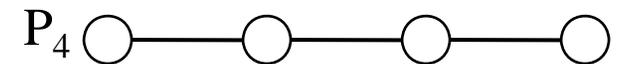

Image by MIT OpenCourseWare.

For a complete graph with order  $n$ ,  $K_n$ , the size  $m$  is:

# Paths and Cycles

- Paths and cycles are two classes of graphs.
- For  $n \geq 1$ , the path  $P_n$  is a graph of order  $n$  and size  $n-1$  whose vertices are  $v_1, v_2, \dots, v_n$ , and whose edges are  $v_i v_{i+1}$  for  $i=1, \dots, n-1$ .
- For  $n \geq 3$ , the **cycle  $C_n$  is a graph of order  $n$  and size  $n$**  whose vertices can be labeled by  $v_1, v_2, \dots, v_n$  and whose edges are  $v_1 v_n$ , and  $v_i v_{i+1}$  for  $i=1, 2, n-1$ . The cycle  $C_n$  is also referred to as an  $n$ -cycle.
- Note every cycle has vertices with the same number of degree: 2, and the number of edges in the cycle = number of vertices

# Walks

- In a graph, we may wish to know if a route exists from one vertex to another- two vertices may not be adjacent, but maybe connected through a *sequence* of edges.
- A walk in a graph  $G$  is an alternating sequence of vertices and edges :

$$v_0 e_0 v_1 e_1 v_2 \dots v_{k-1} e_{k-1} v_k$$

where  $k \geq 1$  and  $e_i$  is incident with  $v_i$  and  $v_{i+1}$  for each  $i = 0, 1, \dots, k-1$

- The vertices and edges need not be distinct
- The length of the walk  $W$  is defined as ' $k$ ' which is the number of occurrences of edges in the sequence.

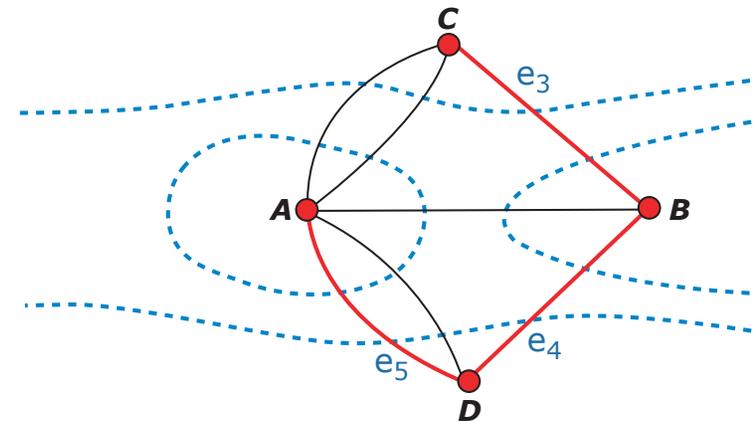

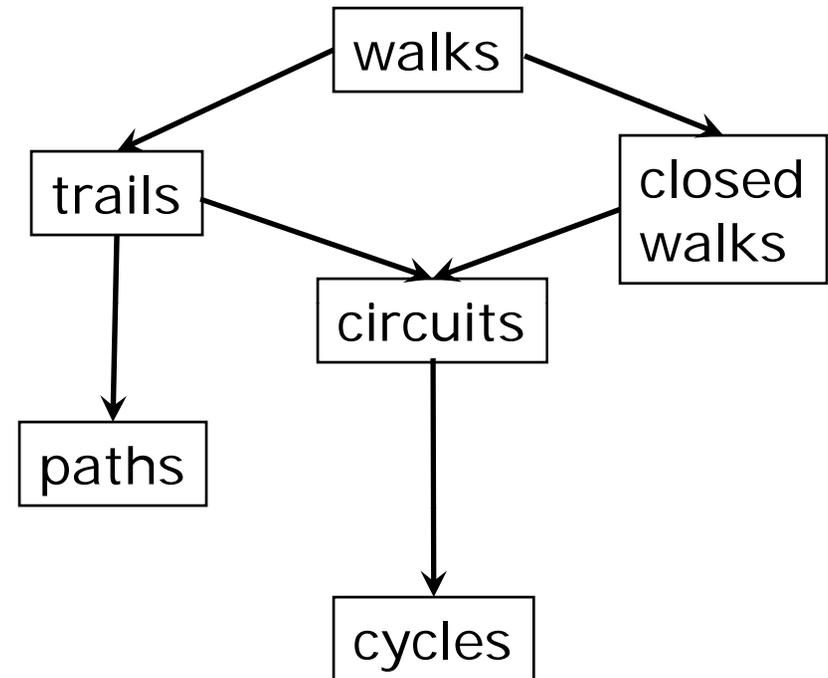

Image by MIT OpenCourseWare.

C e<sub>3</sub> B e<sub>4</sub> D e<sub>5</sub> A

what is the length of this walk?

# Trails and Circuits

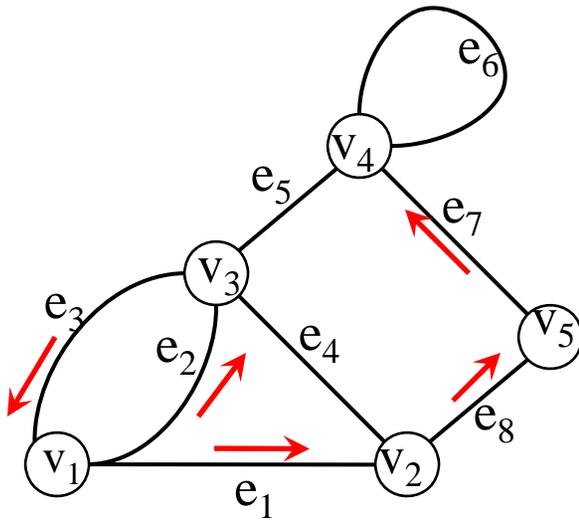

- A *trail* in  $G$  is a walk with all of its edges  $e_1 e_2 \dots e_k$  distinct
- A *path* in  $G$  is a walk with all of its vertices  $v_0 v_1 \dots v_k$  distinct
- For vertices  $u$  and  $v$  in  $G$ , a  $u, v$ -walk (or trail, path etc.) is one with initial vertex  $u$  and final vertex  $v$ .
- A walk or trail of length at least 1 is closed if the initial and final vertex are the same. A closed trail is also called a circuit.
- A cycle is a closed walk with distinct vertices except for the initial and final vertex, which are the same.

Ref [4]

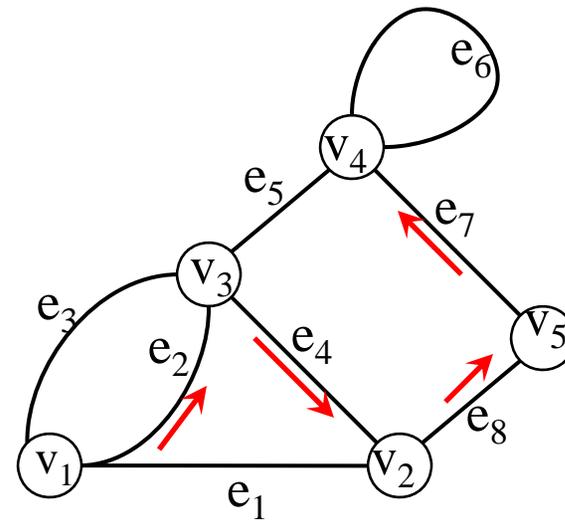

# Examples

- The walk  $t$  is a trail of length 5:  
 $t = (v_1, e_2, v_3, e_3, v_1, e_1, v_2, e_8, v_5, e_7, v_4)$   
 $t$  is not a path since  $v_1$  appears twice

Ref [4]

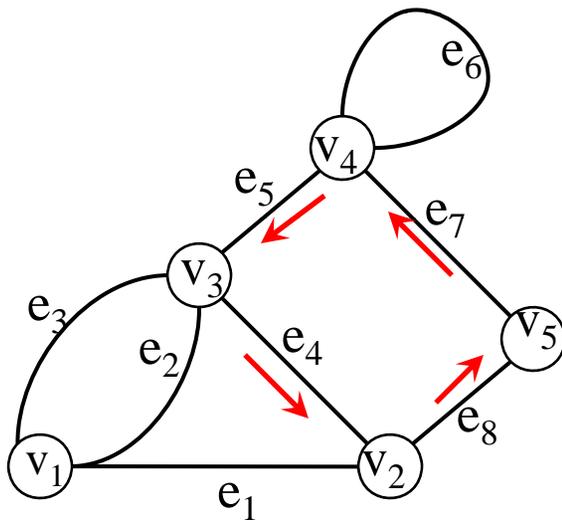

- The walk  $p$  is a path of length 4:  
 $p = (v_1, e_2, v_3, e_4, v_2, e_8, v_5, e_7, v_4)$

Ref [4]

# Examples

- The walk  $c$  is a cycle of length 4:  
 $c = (v_3, e_4, v_2, e_8, v_5, e_7, v_4, e_5, v_3)$

Ref [4]

# Connectivity

- A graph  $G$  is **connected** if every two vertices in  $G$  are joined by a path.
- A graph is disconnected if it is not connected.
- A path in  $G$  that includes every vertex in  $G$  is called a **Hamiltonian path** of  $G$ .
- A cycle in  $G$  that includes every vertex in  $G$  is called a **Hamiltonian cycle** of  $G$ .
- If  $G$  contains a Hamiltonian cycle, then  $G$  is called a **Hamiltonian graph**.

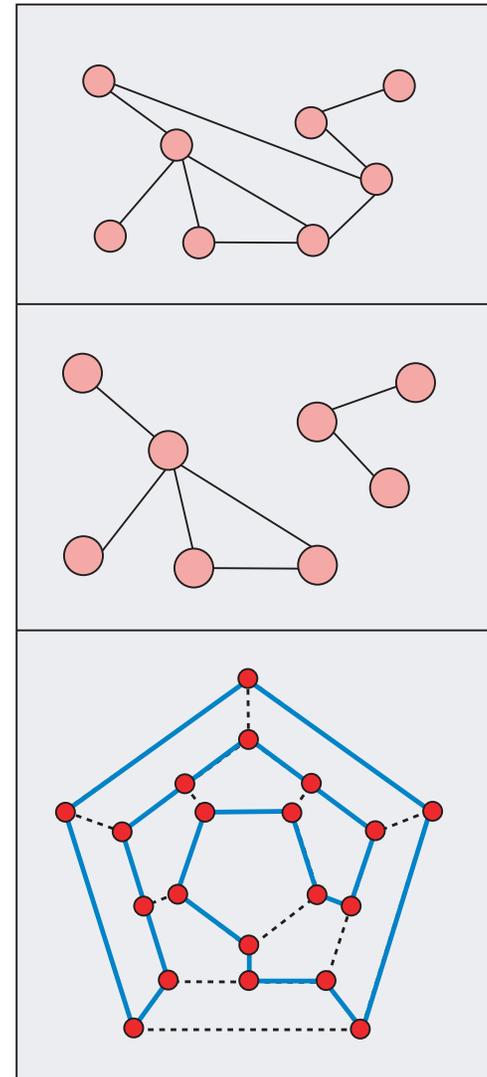

Image by MIT OpenCourseWare.

# Trees

- A tree,  $T$ , is a connected graph that has no cycle as a subgraph
- A tree is a simple graph on  $n$  vertices—a tree cannot have any loops or multiple edges between two vertices.
- $T$  has  $n-1$  edges and is connected.
- A vertex  $v$  of a simple graph is called a leaf if  $d(v) = 1$ .
- Between every pair of distinct vertices in  $T$  there is exactly one path.
- Trees are useful in modeling applications such as hierarchy in a business, directories in an operating system, computer networks.

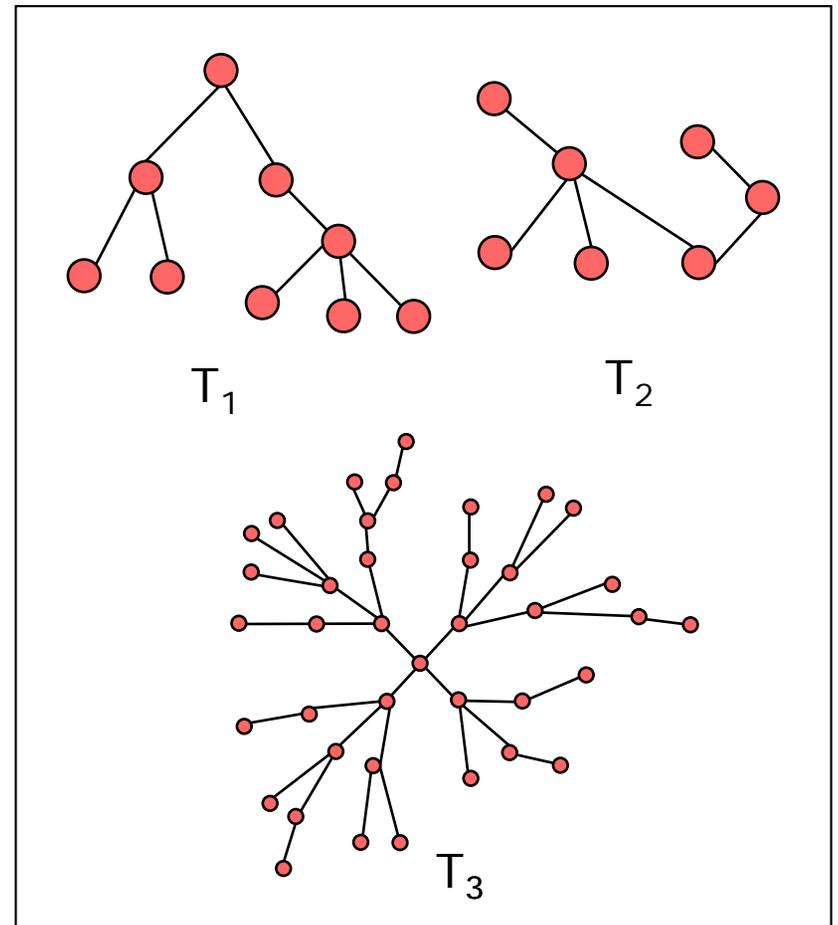

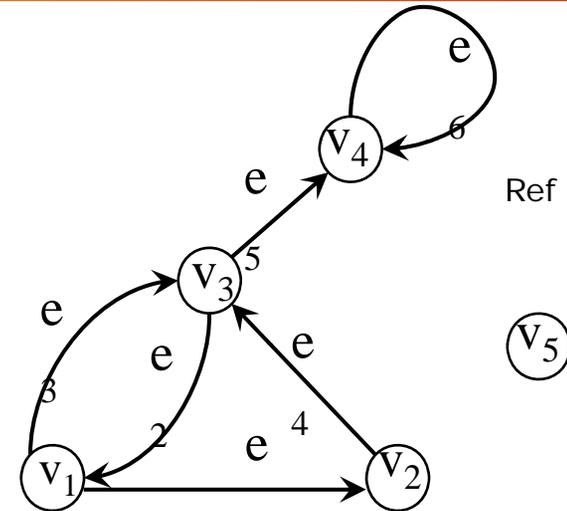

Image by MIT OpenCourseWare.

# Directed Graphs

- A directed graph, or **digraph**  $G$ , consists of *directed* edges (represented with arrows).
- In a directed edge  $uv$ , the vertex  $u$  is called the *tail* and vertex  $v$  is called the *head* of the edge.
- The *indegree*  $d^-(v)$  of a vertex  $v$  is number of directed edges having  $v$  as head.
- The *outdegree*  $d^+(v)$  of  $v$  is number of directed edges having  $v$  as tail.
- For a digraph:

$$\sum_{i=1}^n d^-(v_i) = \sum_{i=1}^n d^+(v_i) = m$$

Ref [4]

	$d^-(v_i)$	$d^+(v_i)$
$v_1$		
$v_2$		
$v_3$		
$v_4$		
$v_5$		

# Weighted Graphs

- A connected graph  $G$  is called a **weighted graph** if each edge  $e$  in  $G$  is assigned a number  $w(e)$ , called the weight of  $e$ .
- Depending on the application, the weight of an edge may be a measure of physical distance, time consumed, cost, capacity, or some other quantity of interest.
- Given a walk  $W$  in a weighted graph, the weight of  $W$ , is the sum of the weights of the edges contained in  $W$ .

## Traveling Salesman Problem

A traveling salesman wants to make a round trip through  $n$  cities,  $c_1..c_i..c_n$ . He starts in  $c_1$ , visits each remaining city  $c_i$  exactly once, and ends in  $c_1$  where he started the trip.

If he knows the distances between every pair of cities  $c_i$  and  $c_j$ , how should he plan his round trip to make the total round-trip distance as short as possible?

The problem of finding the shortest route is that of finding a minimum weight Hamiltonian cycle of the weighted complete graph  $K_n$ .

# Application Example: Project Graphs and Critical Paths

- A project consists of a collection of tasks.
- Each task has an associated completion time.
- A task may depend on other tasks to be completed before it can be initiated.
- A project graph can be constructed, such that the vertices represent tasks, and edges represent task dependencies.
- The total time of a path is the sum of completion time of each task on that path.
- **The path with longest total time is the critical path**
- The critical path determines project completion time.

Job #	Immediate Predecessors	Time [min]
A		0
B	A	10
C	A	20
D	B,C	30
E	B,C	20
F	E	40
G	D,F	20
H	G	0

# k-regular graphs

- A graph  $g$  is called  $k$ -regular if  $d(v_i) = k$  for all  $v_i$  in  $G$ .
- The null graph is a 0-regular graph.
- The cycle  $C_n$  is a 2-regular graph.
- A complete graph is an  $(n-1)$  regular graph.

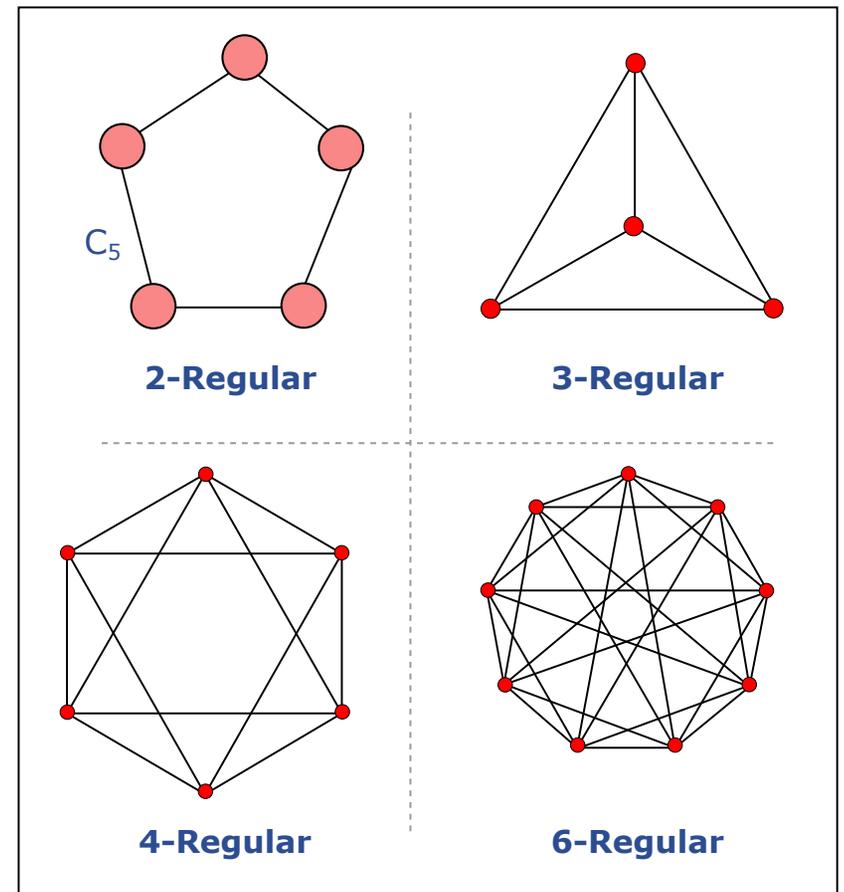

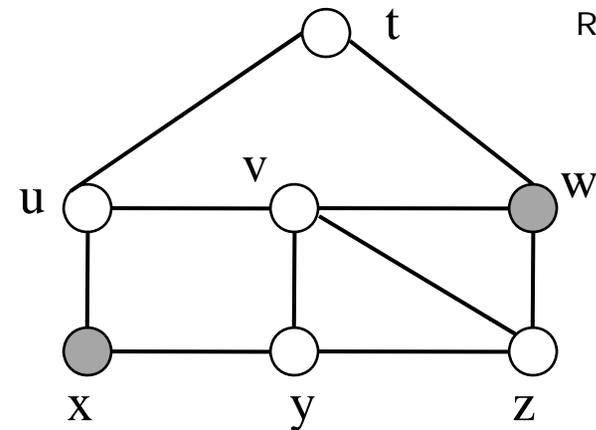

Image by MIT OpenCourseWare.

# Distance

- **The distance** from vertex  $v_1$  to  $v_2$ ,  $d(v_1, v_2)$  in a connected graph  $G$  is **the smallest length of all  $v_1 - v_2$  paths** in  $G$ .
- The shortest path through the network from one vertex to another is also called the **'geodesic path'**.
- There may be and often is more than one geodesic path between two vertices.

Ref [3]

x-w path	length

$d(x, w) =$

# Diameter

- The greatest distance (longest path) between any two vertices in a graph  $G$  is called the **diameter** of  $G$ .
- The diameter is the **longest geodesic path** between any two vertices in the network.
- The diameter of a graph is an indication of how far apart are its vertices.

## Diameter of our World

- We may model our world as a collection of people – each person is a vertex (node) and two people (vertices) are connected if they are acquainted. What will be the diameter of this graph (or social network)?

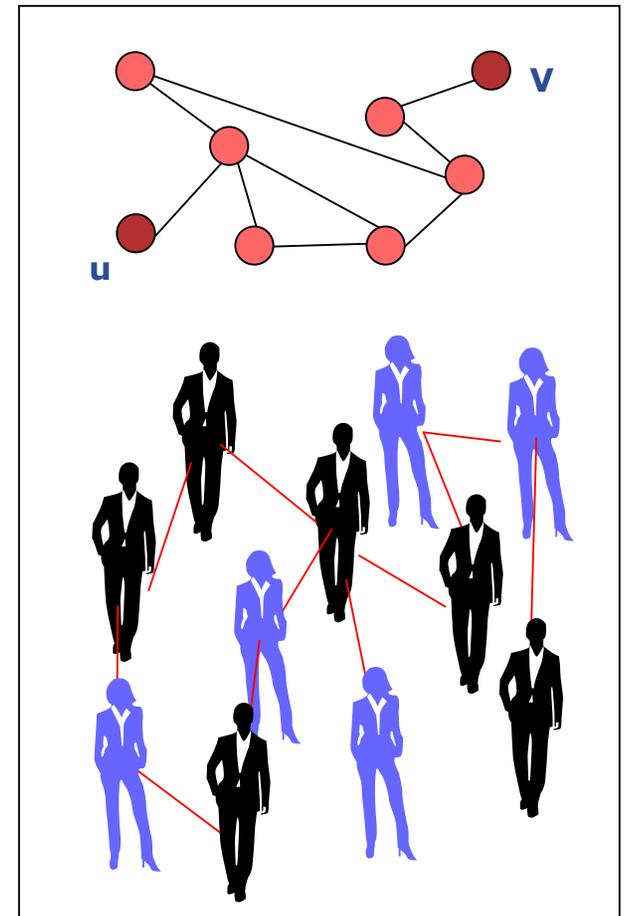

Image by MIT OpenCourseWare.

# Small World Networks

- Small world networks are ‘highly clustered’, yet have small characteristic path lengths.
- Neural networks, power grids, collaboration graphs of film actors, and many other systems form ‘small world’ networks.
- In small world networks there are ‘short cuts’ that shorten the distance between vertices.
- Signal propagation speed is enhanced in such systems; rumors can spread quickly, the number of legs in an air or train journey is small, infectious diseases spread more easily in a population etc.

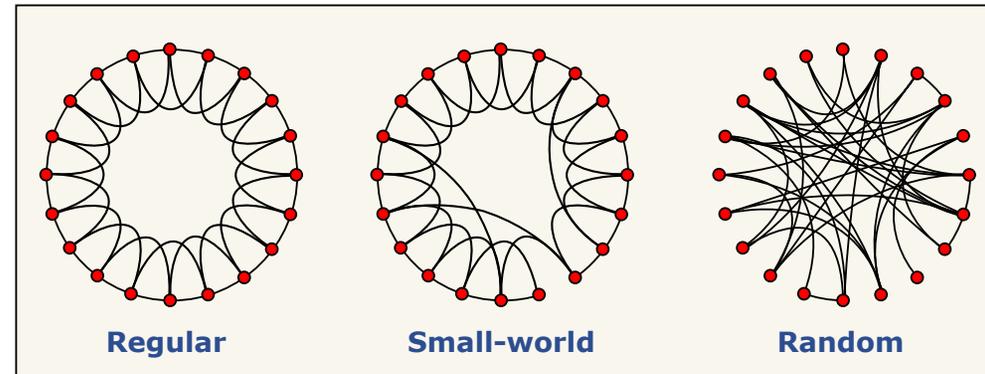

Image by MIT OpenCourseWare.
