CHAPTER 5

Integrals

5.1 The Idea of the Integral

This chapter is about the idea of integration, and also about the technique of integration. We explain how it is done in principle, and then how it is done in practice. Integration is a problem of adding up infinitely many things, each of which is infinitesimally small. Doing the addition is not recommended. The whole point of calculus is to offer a better way.

The problem of integration is to find a limit of sums. The key is to work backward from a limit of differences (which is the derivative). We can integrate \( v(x) \) if it turns up as the derivative of another function \( f(x) \). The integral of \( v = \cos x \) is \( f = \sin x \). The integral of \( v = x \) is \( f = \frac{1}{2} x^2 \). Basically, \( f(x) \) is an "antiderivative". The list of \( f \)'s will grow much longer (Section 5.4 is crucial). A selection is inside the cover of this book. If we don't find a suitable \( f(x) \), numerical integration can still give an excellent answer.

I could go directly to the formulas for integrals, which allow you to compute areas under the most amazing curves. (Area is the clearest example of adding up infinitely many infinitely thin rectangles, so it always comes first. It is certainly not the only problem that integral calculus can solve.) But I am really unwilling just to write down formulas, and skip over all the ideas. Newton and Leibniz had an absolutely brilliant intuition, and there is no reason why we can't share it.

They started with something simple. We will do the same.

SUMS AND DIFFERENCES

Integrals and derivatives can be mostly explained by working (very briefly) with sums and differences. Instead of functions, we have \( n \) ordinary numbers. The key idea is nothing more than a basic fact of algebra. In the limit as \( n \to \infty \), it becomes the basic fact of calculus. The step of "going to the limit" is the essential difference between algebra and calculus! It has to be taken, in order to add up infinitely many infinitesimals—but we start out this side of it.

To see what happens before the limiting step, we need two sets of \( n \) numbers. The first set will be \( v_1, v_2, \ldots, v_n \), where \( v \) suggests velocity. The second set of numbers will be \( f_1, f_2, \ldots, f_n \), where \( f \) recalls the idea of distance. You might think \( d \) would be a better symbol for distance, but that is needed for the \( dx \) and \( dy \) of calculus.
A first example has $n = 4$:

\[ v_1, v_2, v_3, v_4 = 1, 2, 3, 4 \quad f_1, f_2, f_3, f_4 = 1, 3, 6, 10. \]

The relation between the $v$'s and $f$'s is seen in that example. When you are given $1, 3, 6, 10$, how do you produce $1, 2, 3, 4$? By taking differences. The difference between $10$ and $6$ is $4$. Subtracting $6 - 3$ is $3$. The difference $f_2 - f_1 = 3 - 1$ is $v_2 = 2$. Each $v$ is the difference between two $f$'s:

\[ v_j \text{ is the difference } f_j - f_{j-1}. \]

This is the discrete form of the derivative. I admit to a small difficulty at $j = 1$, from the fact that there is no $f_0$. The first $v$ should be $f_1 - f_0$, and the natural idea is to agree that $f_0$ is zero. This need for a starting point will come back to haunt us (or help us) in calculus.

Now look again at those same numbers—but start with $v$. From $v = 1, 2, 3, 4$ how do you produce $f = 1, 3, 6, 10$? By taking sums. The first two $v$'s add to $3$, which is $f_2$. The first three $v$'s add to $f_3 = 6$. The sum of all four $v$'s is $1 + 2 + 3 + 4 = 10$. Taking sums is the opposite of taking differences.

That idea from algebra is the key to calculus. The sum $f_j$ involves all the numbers $v_1 + v_2 + \cdots + v_j$. The difference $v_j$ involves only the two numbers $f_j - f_{j-1}$. The fact that one reverses the other is the “Fundamental Theorem.” Calculus will change sums to integrals and differences to derivatives—but why not let the key idea come through now?

5A Fundamental Theorem of Calculus (before limits):

If each $v_j = f_j - f_{j-1}$, then $v_1 + v_2 + \cdots + v_n = f_n - f_0$.

The differences of the $f$'s add up to $f_n - f_0$. All $f$'s in between are canceled, leaving only the last $f_n$ and the starting $f_0$. The sum “telescopes”:

\[ v_1 + v_2 + v_3 + \cdots + v_n = (f_1 - f_0) + (f_2 - f_1) + (f_3 - f_2) + \cdots + (f_n - f_{n-1}). \]

The number $f_1$ is canceled by $-f_1$. Similarly $-f_2$ cancels $f_2$ and $-f_3$ cancels $f_3$. Eventually $f_n$ and $-f_0$ are left. When $f_0$ is zero, the sum is the final $f_n$.

That completes the algebra. We add the $v$'s by finding the $f$'s.

**Question** How do you add the odd numbers $1 + 3 + 5 + \cdots + 99$ (the $v$'s)?

**Answer** They are the differences between $0, 1, 4, 9, \ldots$. These $f$'s are squares. By the Fundamental Theorem, the sum of $50$ odd numbers is $(50)^2$.

The tricky part is to discover the right $f$'s! Their differences must produce the $v$'s. In calculus, the tricky part is to find the right $f(x)$. Its derivative must produce $v(x)$. It is remarkable how often $f$ can be found—more often for integrals than for sums. Our next step is to understand how the integral is a limit of sums.

**SUMS APPROACH INTEGRALS**

Suppose you start a successful company. The rate of income is increasing. After $x$ years, the income per year is $\sqrt{x}$ million dollars. In the first four years you reach $\sqrt{1}, \sqrt{2}, \sqrt{3},$ and $\sqrt{4}$ million dollars. Those numbers are displayed in a bar graph (Figure 5.1a, for investors). I realize that most start-up companies make losses, but your company is an exception. If the example is too good to be true, please keep reading.
The graph shows four rectangles, of heights $\sqrt{1}$, $\sqrt{2}$, $\sqrt{3}$, $\sqrt{4}$. Since the base of each rectangle is one year, those numbers are also the areas of the rectangles. One investor, possibly weak in arithmetic, asks a simple question: *What is the total income for all four years?* There are two ways to answer, and I will give both.

The first answer is $\sqrt{1} + \sqrt{2} + \sqrt{3} + \sqrt{4}$. Addition gives 6.15 million dollars. Figure 5.1b shows this total—which is reached at year 4. This is exactly like velocities and distances, but now $v$ is the income per year and $f$ is the total income. Algebraically, $f_4$ is still $v_1 + \cdots + v_4$.

The second answer comes from geometry. The total income is the total area of the rectangles. We are emphasizing the correspondence between addition and area. That point may seem obvious, but it becomes important when a second investor (smarter than the first) asks a harder question.

Here is the problem. *The incomes as stated are false.* The company did not make a million dollars the first year. After three months, when $x$ was 1/4, the rate of income was only $\sqrt{x} = 1/2$. The bar graph showed $\sqrt{1} = 1$ for the whole year, but that was an overstatement. The income in three months was not more than 1/2 times 1/4, the rate multiplied by the time.

All other quarters and years were also overstated. Figure 5.2a is closer to reality, with 4 years divided into 16 quarters. It gives a new estimate for total income.

Again there are two ways to find the total. We add $\sqrt{1/4} + \sqrt{2/4} + \ldots + \sqrt{16/4}$, remembering to multiply them all by 1/4 (because each rate applies to 1/4 year). This is also the area of the 16 rectangles. The area approach is better because the 1/4 is automatic. Each rectangle has base 1/4, so that factor enters each area. The total area is now 5.56 million dollars, closer to the truth.

You see what is coming. The next step divides time into weeks. After one week the rate $\sqrt{x}$ is only $\sqrt{1/52}$. That is the height of the first rectangle—its base is $\Delta x = 1/52$. There is a rectangle for every week. Then a hard-working investor divides time into days, and the base of each rectangle is $\Delta x = 1/365$. At that point there are $4 \times 365 = 1460$ rectangles, or 1461 because of leap year, with a total area below $5\frac{1}{2}$
Integrals

Total income

\[ I = \text{area of rectangles} \]

\[ I = \frac{1}{4} \left( \sqrt{1} + \sqrt{2} + \cdots + \sqrt{16} \right) \]

million dollars. The calculation is elementary but depressing—adding up thousands of square roots, each multiplied by \( \Delta x \) from the base. There has to be a better way.

The better way, in fact the best way, is calculus. The whole idea is to allow for continuous change. The geometry problem is to find the area under the square root curve. That question cannot be answered by arithmetic, because it involves a limit.

The rectangles have base \( \Delta x \) and heights \( \sqrt{1}, \sqrt{2}, \cdots, \sqrt{16} \). There are \( 4/\Delta x \) rectangles—more and more terms from thinner and thinner rectangles. The area is the limit of the sum as \( \Delta x \to 0 \).

This limiting area is the "integral." We are looking for a number below 54.

**Algebra (area of \( n \) rectangles):** Compute \( v_1 + \cdots + v_n \) by finding \( f \)'s.

Key idea: If \( v_j = f_j - f_{j-1} \) then the sum is \( f_n - f_0 \).

**Calculus (area under curve):** Compute the limit of \( \Delta x \left[ v(\Delta x) + v(2\Delta x) + \cdots \right] \).

Key idea: If \( v(x) = df/dx \) then area = integral to be explained next.

**5.1 EXERCISES**

Read-through questions

The problem of summation is to add \( v_1 + \cdots + v_n \). It is solved if we find \( f \)'s such that \( v_j = \text{area} \). Then \( v_1 + \cdots + v_n \) equals \( \text{area} \). The cancellation in \( (f_1 - f_0) + (f_2 - f_1) + \cdots + (f_n - f_{n-1}) \) leaves only \( \text{area} \). Taking sums is the \( \text{area} \) of taking differences.

The differences between 0, 1, 4, 9 are \( v_1, v_2, v_3 = \text{area} \). For \( f_2 - f_1 \) the difference between \( f_{10} \) and \( f_10 \) is \( v_{10} = \text{area} \). From this pattern \( 1 + 3 + 5 + \cdots + 19 \) equals \( \text{area} \).

For functions, finding the integral is the reverse of \( \text{area} \). If the derivative of \( f(x) \) is \( v(x) \), then the \( f(x) \) of \( v(x) \) is \( f(x) \).

If \( v(x) = 10x \) then \( f(x) = \frac{1}{10}x^2 \). This is the \( \text{area} \) of a triangle with base \( x \) and height \( 10x \).

Integrals begin with sums. The triangle under \( v = 10x \) out to \( x = 4 \) has area \( \text{area} \). It is approximated by four rectangles of heights 10, 20, 30, 40 and area \( \text{area} \). It is better approximated by eight rectangles of heights \( \text{area} \) and area \( \text{area} \).

For \( n \) rectangles covering the triangle the area is the sum of \( \text{area} \). As \( n \to \infty \) this sum should approach the number \( \text{area} \). That is the integral of \( v = 10x \) from 0 to 4.
5.1 The Idea of the Integral

Problems 1–6 are about sums \( f_j \) and differences \( v_j \).

1. With \( v = 1, 2, 4, 8 \), the formula for \( v_j \) is \( \text{______} \) (not \( 2^j \)). Find \( f_1, f_2, f_3, f_4 \) starting from \( f_0 = 0 \). What is \( f_7 \)?

2. The same \( v = 1, 2, 4, 8, \ldots \) are the differences between \( f = 1, 2, 4, 8, 16, \ldots \). Now \( f_0 = 1 \) and \( f_j = 2^j \).

3. The differences between \( f = 1, 1/2, 1/4, 1/8 \) are \( v = -1/2, -1/4, -1/8 \). These negative \( v \)'s do not add up to these positive \( f \)'s. Verify that \( v_1 + v_2 + v_3 = f_4 - f_3 \) is still true.

4. Any constant \( C \) can be added to the antiderivative \( f(x) \) because the \( \text{______} \) of a constant is zero. Any \( C \) can be added to \( f_0, f_1, \ldots \) because the \( \text{______} \) between the \( f \)'s is not changed.

5. Show that \( f_2 = r^2 (r - 1) \) has \( f_j - f_{j-1} = r^{j-1} \). Therefore the geometric series \( 1 + r + \cdots + r^{j-1} \) adds up to \( \text{______} \) (remember to subtract \( f_0 \)).

6. The sums \( f_j = (r^{j-1}) (r - 1) \) also have \( f_j - f_{j-1} = r^{j-1} \). Now \( f_0 = \text{______} \). Therefore \( 1 + r + \cdots + r^{j-1} \) adds up to \( f_j \). The sum \( 1 + r + \cdots + r^n \) equals \( \text{______} \).

7. Suppose \( t(x) = 3 \) for \( x < 1 \) and \( t(x) = 7 \) for \( x > 1 \). Find the area \( f(x) \) from 0 to \( x \), under the graph of \( t(x) \). (Two pieces.)

8. If \( n = 1, -2, 3, -4, \ldots \), write down the \( f \)'s starting from \( f_0 = 0 \). Find formulas for \( t_j \) and \( f_j \) when \( j \) is odd and \( j \) is even.

Problems 9–16 are about the company earning \( \sqrt{x} \) per year.

9. When time is divided into weeks there are \( 4 \times 52 = 208 \) rectangles. Write down the first area, the 208th area, and the \( j \)th area.

10. How do you know that the sum over 208 weeks is smaller than the sum over 16 quarters?

11. A pessimist would use \( \sqrt{x} \) at the \( \text{beginning} \) of each time period as the income rate for that period. Redraw Figure 5.1 (both parts) using heights \( \sqrt{0}, \sqrt{1/4}, \sqrt{1}, \sqrt{2}, \sqrt{3} \). How much lower is the estimate of total income?

12. The same pessimist would redraw Figure 5.2 with heights \( 0, \sqrt{1/4}, \ldots \). What is the height of the last rectangle? How much does this change reduce the total rectangular area 5.56?

13. At every step from years to weeks to days to hours, the pessimist's area goes \( \text{______} \) and the optimist's area goes \( \text{______} \). The difference between them is the area of the last \( \text{______} \).

14. The optimist and pessimist arrive at the same limit as years are divided into weeks, days, hours, seconds. Draw the \( \sqrt{x} \) curve between the rectangles to show why the pessimist is always too low and the optimist is too high.

15. (Important) Let \( f(x) \) be the area under the \( \sqrt{x} \) curve, above the interval from 0 to \( x \). The area to \( x + \Delta x \) is \( f(x + \Delta x) \). The extra area is \( \Delta f = \frac{1}{2} \Delta x \). This is almost a rectangle with base \( \Delta x \) and height \( \sqrt{x} \). So \( \Delta f/\Delta x \) is close to \( \text{______} \).

As \( \Delta x \to 0 \) we suspect that \( df/dx = \text{______} \).

16. Draw the \( \sqrt{x} \) curve from \( x = 0 \) to 4 and put triangles below to prove that the area under it is more than 5. Look left and right from the point where \( \sqrt{1} = 1 \).

Problems 17–22 are about a company whose expense rate \( v(x) = 6 - x \) is decreasing.

17. The expenses drop to zero at \( x = \text{______} \). The total expense during those years equals \( \text{______} \). This is the area of \( \text{______} \).

18. The rectangles of heights \( 6, 5, 4, 3, 2, 1 \) give a total estimated expense of \( \text{______} \). Draw them enclosing the triangle to show why this total is too high.

19. How many rectangles (enclosing the triangle) would you need before their areas are within 1 of the correct triangular area?

20. The accountant uses 2-year intervals and computes \( v = 5, 3, 1 \) at the midpoints (the odd-numbered years). What is her estimate, how accurate is it, and why?

21. What is the area \( f(x) \) under the line \( t(x) = 6 - x \) above the interval from 2 to \( x \)? What is the derivative of this \( f(x) \)?

22. What is the area \( f(x) \) under the line \( t(x) = 6 - x \) above the interval from \( x \) to 6? What is the derivative of this \( f(x) \)?

23. With \( \Delta x = 1/3 \), find the area of the three rectangles that enclose the graph of \( t(x) = x^2 \).

24. Draw graphs of \( v = \sqrt{x} \) and \( v = x^2 \) from 0 to 1. Which areas add to \( 1 \)? The same is true for \( r = x^3 \) and \( v = \text{______} \).

25. From \( x \) to \( x + \Delta x \), the area under \( v = x^2 \) is \( \Delta f \). This is almost a rectangle with base \( \Delta x \) and height \( \text{______} \). So \( \Delta f/\Delta x \) is close to \( \text{______} \). In the limit we find \( df/dx = x^2 \) and \( f(x) = \text{______} \).

26. Compute the area of 208 rectangles under \( t(x) = \sqrt{x} \) from \( x = 0 \) to \( x = 4 \).
The symbol ∫ was invented by Leibniz to represent the integral. It is a stretched-out S, from the Latin word for sum. This symbol is a powerful reminder of the whole construction: *Sum approaches integral, S approaches ∫, and rectangular area approaches curved area:*

\[
\text{curved area} = \int v(x) \, dx = \int \sqrt{x} \, dx. \tag{1}
\]

The rectangles of base Δx lead to this limit—the integral of \(\sqrt{x}\). The “dx” indicates that Δx approaches zero. The heights \(v_j\) of the rectangles are the heights \(v(x)\) of the curve. The sum of \(v_j\) times Δx approaches “the integral of \(v\) of \(x\) dx.” You can imagine an infinitely thin rectangle above every point, instead of ordinary rectangles above special points.

We now find the area under the square root curve. The “limits of integration” are 0 and 4. The lower limit is \(x = 0\), where the area begins. *(The start could be any point \(x = a\).)* The upper limit is \(x = 4\), since we stop after four years. *(The finish could be any point \(x = b\).)* The area of the rectangles is a sum of base Δx times heights \(\sqrt{x}\). The curved area is the limit of this sum. *That limit is the integral of \(\sqrt{x}\) from 0 to 4:*

\[
\lim_{\Delta x \to 0} \left[ (\sqrt{\Delta x})(\Delta x) + (\sqrt{2\Delta x})(\Delta x) + \cdots + (\sqrt{4})(\Delta x) \right] = \int_{x = 0}^{x = 4} \sqrt{x} \, dx. \tag{2}
\]

The outstanding problem of integral calculus is still to be solved. *What is this limiting area?* We have a symbol for the answer, involving ∫ and \(\sqrt{x}\) and \(dx\)—but we don’t have a number.

**THE ANTIDERIVATIVE**

I wish I knew who discovered the area under the graph of \(\sqrt{x}\). It may have been Newton. The answer was available earlier, but the key idea was shared by Newton and Leibniz. They understood the parallels between sums and integrals, and between differences and derivatives. I can give the answer, by following that analogy. I can’t give the proof (yet)—it is the Fundamental Theorem of Calculus.

In algebra the difference \(f_j - f_{j-1}\) is \(v_j\). When we add, the sum of the \(v\)’s is \(f_n - f_0\). *In calculus the derivative of \(f(x)\) is \(v(x)\).* When we integrate, *the area under the \(v(x)\) curve is \(f(x)\) minus \(f(0)\).* Our problem asks for the area out to \(x = 4\):

\[
\text{If } df/dx = \sqrt{x} \text{ then area } = \int_{x = 0}^{x = 4} \sqrt{x} \, dx = f(4) - f(0). \tag{3}
\]

What is \(f(x)\)? Instead of the derivative of \(\sqrt{x}\), we need its “antiderivative.” We have to find a function \(f(x)\) whose derivative is \(\sqrt{x}\). It is the opposite of Chapters 2–4, and requires us to work backwards. The derivative of \(x^n\) is \(nx^{n-1}\)—now we need the antiderivative. The quick formula is \(f(x) = x^{n+1}/(n + 1)\)—we aim to understand it.

Solution Since the derivative lowers the exponent, the antiderivative raises it. We go from \(x^{1/2}\) to \(x^{3/2}\). But then the derivative is \((3/2)x^{1/2}\). It contains an unwanted factor \(3/2\). To cancel that factor, put \(2/3\) into the antiderivative:

\[
f(x) = \frac{2}{3}x^{3/2} \text{ has the required derivative } v(x) = x^{1/2} = \sqrt{x}.
\]
There you see the key to integrals: Work backward from derivatives (and adjust).

Now comes a number—the exact area. At \( x = 4 \) we find \( x^{3/2} = 8 \). Multiply by \( 2/3 \) to get \( 16/3 \). Then subtract \( f(0) = 0 \):

\[
\int_{x=0}^{x=4} \sqrt{x} \, dx = \frac{2}{3} (4)^{3/2} - \frac{2}{3} (0)^{3/2} = \frac{2}{3} (8) = \frac{16}{3}
\]

The total income over four years is \( 16/3 = 5\frac{1}{3} \) million dollars. This is \( f(4) - f(0) \). The sum from thousands of rectangles was slowly approaching this exact area \( 5\frac{1}{3} \).

Other areas The income in the first year, at \( x = 1 \), is \( \frac{2}{3}(1)^{3/2} = \frac{2}{3} \) million dollars. (The false income was 1 million dollars.) The total income after \( x \) years is \( \frac{2}{3} x^{3/2} \), which is the antiderivative \( f(x) \). The square root curve covers 2/3 of the overall rectangle it sits in. The rectangle goes out to \( x \) and up to \( \sqrt{x} \), with area \( x^{3/2} \), and 2/3 of that rectangle is below the curve. (1/3 is above.)

Other antiderivatives The derivative of \( x^5 \) is \( 5x^4 \). Therefore the antiderivative of \( x^4 \) is \( x^5/5 \). Divide by 5 (or \( n + 1 \)) to cancel the 5 (or \( n + 1 \)) from the derivative. And don't allow \( n + 1 = 0 \):

The derivative \( v(x) = x^n \) has the antiderivative \( f(x) = x^{n+1}/(n + 1) \).

**EXAMPLE 1** The antiderivative of \( x^2 \) is \( \frac{1}{3} x^3 \). This is the area under the parabola \( v(x) = x^2 \). The area out to \( x = 1 \) is \( \frac{1}{3}(1)^3 - \frac{1}{3}(0)^3 \), or \( 1/3 \).

Remark on \( \sqrt{x} \) and \( x^2 \) The 2/3 from \( \sqrt{x} \) and the 1/3 from \( x^2 \) add to 1. Those are the areas below and above the \( \sqrt{x} \) curve, in the corner of Figure 5.3. If you turn the curve by 90°, it becomes the parabola. The functions \( y = \sqrt{x} \) and \( x = y^2 \) are inverses! The areas for these inverse functions add to a square of area 1.

**AREA UNDER A STRAIGHT LINE**

You already know the area of a triangle. The region is below the diagonal line \( v = x \) in Figure 5.4. The base is 4, the height is 4, and the area is \( \frac{1}{2}(4)(4) = 8 \). Integration is
not required! But if you allow calculus to repeat that answer, and build up the integral \( f(x) = \frac{1}{2}x^2 \) as the limiting area of many rectangles, you will have the beginning of something important.

The four rectangles have area \( 1 + 2 + 3 + 4 = 10 \). That is greater than 8, because the triangle is inside. 10 is a first approximation to the triangular area 8, and to improve it we need more rectangles.

The next rectangles will be thinner, of width \( \Delta x = \frac{1}{2} \) instead of the original \( \Delta x = 1 \). There will be eight rectangles instead of four. They extend above the line, so the answer is still too high. The new heights are \( \frac{1}{2}, 1, \frac{3}{2}, 2, \frac{5}{2}, 3, \frac{7}{2}, 4 \). The total area in Figure 5.4b is the sum of the base \( \Delta x = \frac{1}{2} \) times those heights:

\[
\text{area} = \left( \frac{1}{2} + 1 + \frac{3}{2} + 2 + \cdots + 4 \right) = 9 \text{ (which is closer to 8)}.
\]

**Question** What is the area of 16 rectangles? Their heights are \( \frac{1}{4}, \frac{1}{2}, \ldots, 4 \).

**Answer** With base \( \Delta x = \frac{1}{4} \) the area is \( \frac{1}{4} \left( \frac{1}{4} + \frac{1}{2} + \cdots + 4 \right) = 8\frac{1}{2} \).

The effort of doing the addition is increasing. A formula for the sums is needed, and will be established soon. (The next answer would be 8\frac{1}{2}.) But more important than the formula is the idea. We are carrying out a limiting process, one step at a time. The area of the rectangles is approaching the area of the triangle, as \( \Delta x \) decreases. The same limiting process will apply to other areas, in which the region is much more complicated. Therefore we pause to comment on what is important.

**Area Under a Curve**

What requirements are imposed on those thinner and thinner rectangles? It is not essential that they all have the same width. And it is not required that they cover the triangle completely. The rectangles could lie below the curve. The limiting answer will still be 8, even if the widths \( \Delta x \) are unequal and the rectangles fit inside the triangle or across it. We only impose two rules:

1. The largest width \( \Delta x_{\text{max}} \) must approach zero.
2. The top of each rectangle must touch or cross the curve.

The area under the graph is defined to be the limit of these rectangular areas, if that limit exists. For the straight line, the limit does exist and equals 8. That limit is independent of the particular widths and heights—as we absolutely insist it should be.

Section 5.5 allows any continuous \( v(x) \). The question will be the same—Does the limit exist? The answer will be the same—Yes. That limit will be the integral of \( v(x) \), and it will be the area under the curve. It will be \( f(x) \).
EXAMPLE 2 The triangular area from 0 to x is \( \frac{1}{2} \text{(base)} \cdot \text{(height)} = \frac{1}{2} f(x) (x) \). That is \( f(x) = \frac{1}{2} x^2 \). Its derivative is \( v(x) = x \). But notice that \( \frac{1}{2} x^2 + 1 \) has the same derivative. So does \( f = \frac{1}{2} x^2 + C \), for any constant C. There is a "constant of integration" in \( f(x) \), which is wiped out in its derivative \( v(x) \).

EXAMPLE 3 Suppose the velocity is decreasing: \( v(x) = 4 - x \). If we sample \( v \) at \( x = 1, 2, 3, 4 \), the rectangles lie under the graph. Because \( v \) is decreasing, the right end of each interval gives \( v_{\text{min}} \). Then the rectangular area \( 3 + 2 + 1 + 0 = 6 \) is less than the exact area 8. The rectangles are inside the triangle, and eight rectangles with base \( \frac{1}{2} \) come closer:

rectangular area = \( \frac{1}{2} (3\frac{1}{2} + 3 + \cdots + \frac{1}{2} + 0) = 7 \).

Sixteen rectangles would have area 7\( \frac{1}{2} \). We repeat that the rectangles need not have the same widths \( \Delta x \), but it makes these calculations easier.

What is the area out to an arbitrary point (like \( x = 3 \) or \( x = 1 \))? We could insert rectangles, but the Fundamental Theorem offers a faster way. Any antiderivative of \( 4 - x \) will give the area. **We look for a function whose derivative is** \( 4 - x \). The derivative of \( 4x \) is 4, the derivative of \( \frac{1}{2} x^2 \) is \( x \), so work backward:

\[
\text{to achieve } df/dx = 4 - x \text{ choose } f(x) = 4x - \frac{1}{2} x^2.
\]

Calculus skips past the rectangles and computes \( f(3) = 7\frac{1}{2} \). The area between \( x = 1 \) and \( x = 3 \) is the difference \( 7\frac{1}{2} - 3\frac{1}{2} = 4 \). In Figure 5.5, this is the area of the trapezoid.

The \( f \)-curve flattens out when the \( v \)-curve touches zero. No new area is being added.

---

**INDEFINITE INTEGRALS AND DEFINITE INTEGRALS**

We have to distinguish two different kinds of integrals. They both use the antiderivative \( f(x) \). The definite one involves the limits 0 and 4, the indefinite one doesn't:

The **indefinite integral** is a function \( f(x) = 4x - \frac{1}{2} x^2 \).

The **definite integral** from \( x = 0 \) to \( x = 4 \) is the **number** \( f(4) - f(0) \).

The definite integral is definitely 8. But the indefinite integral is not necessarily \( 4x - \frac{1}{2} x^2 \). **We can change** \( f(x) \) **by a constant without changing its derivative** (since the
derivative of a constant is zero). The following functions are also antiderivatives:

\[ f(x) = 4x - \frac{1}{2}x^2 + 1, \quad f(x) = 4x - \frac{1}{2}x^2 - 9, \quad f(x) = 4x - \frac{1}{2}x^2 + C. \]

The first two are particular examples. The last is the general case. The constant \( C \) can be anything (including zero), to give all functions with the required derivative. The theory of calculus will show that there are no others. The indefinite integral is the most general antiderivative (with no limits):

\[ \text{indefinite integral } f(x) = \int v(x) \, dx = 4x - \frac{1}{2}x^2 + C. \] (5)

By contrast, the definite integral is a number. It contains no arbitrary constant \( C \). More that that, it contains no variable \( x \). The definite integral is determined by the function \( v(x) \) and the limits of integration (also known as the endpoints). It is the area under the graph between those endpoints.

To see the relation of indefinite to definite, answer this question: What is the definite integral between \( x = 1 \) and \( x = 3 \)? The indefinite integral gives \( f(3) = 7.5 + C \) and \( f(1) = 3 + C \). To find the area between the limits, subtract \( f \) at one limit from \( f \) at the other limit:

\[ \int_{x=1}^{x=3} v(x) \, dx = f(3) - f(1) = (7.5 + C) - (3 + C) = 4. \] (6)

The constant cancels itself! The definite integral is the difference between the values of the indefinite integral. \( C \) disappears in the subtraction.

The difference \( f(3) - f(1) \) is like \( f_a - f_b \). The sum of \( v \) from 1 to \( n \) has become "the integral of \( v(x) \) from 1 to 3." Section 5.3 computes other areas from sums, and 5.4 computes many more from antiderivatives. Then we come back to the definite integral and the Fundamental Theorem:

\[ \int_{a}^{b} v(x) \, dx = \left. \frac{df}{dx} \right|_{a}^{b} = f(b) - f(a). \] (7)

### 5.2 Exercises

**Read-through questions**

Integration yields the _area_ under a curve \( y = v(x) \). It starts from rectangles with base _b_ and heights \( v(x) \) and areas _c_. As \( \Delta x \to 0 \) the area \( v_1 \Delta x + \cdots + v_n \Delta x \) becomes the _integral_ of \( v(x) \). The symbol for the indefinite integral of \( v(x) \) is _d_.

The problem of integration is solved if we find \( f(x) \) such that _f_. Then \( f \) is the _antiderivative_ of \( v \), and \( \int_{a}^{b} v(x) \, dx \) equals _h_ minus _i_. The limits of integration are _j_. This is a _k_ integral, which is a _l_ function \( f(x) \).

The example \( v(x) = x \) has \( f(x) = \frac{x^2}{2} \). It also has \( f(x) = \frac{x^n}{n+1} \). The area under \( v(x) \) from 2 to 6 is _m_. The constant is canceled in computing the difference _n_ minus _o_. If \( v(x) = x^8 \) then \( f(x) = \frac{x^9}{9} \).

The sum \( v_1 + \cdots + v_n = f_n - f_0 \) leads to the Fundamental Theorem \( \int_{a}^{b} v(x) \, dx = \frac{b}{a} \). The _p_ integral is \( f(x) \) and the _q_ integral is \( f(b) - f(a) \). Finding the _r_ under the _s_-graph is the opposite of finding the _t_- of the _u_-graph.

**Find an antiderivative \( f(x) \) for \( v(x) \) in 1–14. Then compute the definite integral \( \int_{a}^{b} v(x) \, dx = f(b) - f(a) \).**

1. \( 5x^2 + 4x^5 \)
2. \( x + 12x^2 \)
3. \( \sqrt[3]{x} \) (or \( x^{1/3} \))
4. \( \sqrt[3]{x} \) (or \( x^{3/2} \))
5. \( x^{1/3} + (2x)^{1/3} \)
6. \( x^{3/2} \)
7. \( 2 \sin x + \sin 2x \)
8. \( \sec^2 x + 1 \)
9. \( x \cos x \) (by experiment)
10. \( x \sin x \) (by experiment)
11. \( \sin x \cos x \)
12. \( \sin^2 x \cos x \)
13. \( 0 \) (find all \( f \))
14. \( -1 \) (find all \( f \))
15. If \( df/dx = v(x) \) then the definite integral of \( v(x) \) from a to b is _m_. If \( f_1 - f_{-1} \) then the definite sum of \( v_1 + \cdots + v_n \) is _m_.
16. The areas include a factor \( \Delta x \), the base of each rectangle. So the sum of \( v \)'s is multiplied by _m_ to approach the integral. The difference of \( f \)'s is divided by _n_ to approach the derivative.
5.3 Summation versus Integration

This section does integration the hard way. We find explicit formulas for \( f = v_1 + \cdots + v_n \). From areas of rectangles, the limits produce the area \( f(x) \) under a curve. According to the Fundamental Theorem, \( df/dx \) should return us to \( v(x) \)—and we verify in each case that it does.

May I recall that there is sometimes an easier way? If we can find an \( f(x) \) whose derivative is \( v(x) \), then the integral of \( v \) is \( f \). Sums and limits are not required, when \( f \) is spotted directly. The next section, which explains how to look for \( f(x) \), will displace this one. (If we can’t find an antiderivative we fall back on summation.) Given a successful \( f \), adding any constant produces another \( f \)—since the derivative of the constant is zero. The right constant achieves \( f(0) = 0 \), with no extra effort.
5 Integrals

This section constructs \( f(x) \) from sums. The next section searches for antiderivatives.

**THE SIGMA NOTATION**

In a section about sums, there has to be a decent way to express them. Consider \( 1^2 + 2^2 + 3^2 + 4^2 \). The individual terms are \( v_j = j^2 \). Their sum can be written in summarization notation, using the capital Greek letter \( \Sigma \) (pronounced sigma):

\[
1^2 + 2^2 + 3^2 + 4^2 \text{ is written } \sum_{j=1}^{4} j^2.
\]

Spoken aloud, that becomes "the sum of \( j^2 \) from \( j = 1 \) to \( 4 \)." It equals 30. The limits on \( j \) (written below and above \( \Sigma \)) indicate where to start and stop:

\[
v_1 + \cdots + v_4 = \sum_{j=1}^{4} v_j \quad \text{and} \quad v_3 + \cdots + v_9 = \sum_{k=3}^{9} v_k.
\]

The \( k \) at the end of (1) makes an additional point. There is nothing special about the letter \( j \). That is a "dummy variable," no better and no worse than \( k \) (or \( i \)). Dummy variables are only on one side (the side with \( \Sigma \)), and they have no effect on the sum. The upper limit \( n \) is on both sides. Here are six sums:

\[
\begin{align*}
\sum_{k=1}^{n} k &= 1 + 2 + 3 + \cdots + n \\
\sum_{j=1}^{4} (j-1)^2 &= 1 + 3 + 5 + 7 = 16 \\
\sum_{j=1}^{5} (2j-1) &= 1 + 3 + 5 + 7 + 9 = 25 \\
\sum_{i=0}^{n} v_i &= v_0 \quad \text{[only one term]} \\
\sum_{j=1}^{4} j^2 &= \frac{4^3}{3} = \frac{64}{3} \\
\sum_{i=0}^{\infty} \frac{1}{2^i} &= 1 + \frac{1}{2} + \frac{1}{4} + \cdots = 2 \quad \text{[infinite series]}
\end{align*}
\]

The numbers 1 and \( n \) or 1 and 4 (or 0 and \( \infty \)) are the lower limit and upper limit. The dummy variable \( i \) or \( j \) or \( k \) is the index of summation. I hope it seems reasonable that the infinite series \( 1 + \frac{1}{2} + \frac{1}{4} + \cdots \) adds to 2. We will come back to it in Chapter 10.

A sum like \( \sum_{j=1}^{6} 6 \) looks meaningless, but it is actually \( 6 + 6 + \cdots + 6 = 6n \). It follows the rules. In fact \( \sum_{j=1}^{n} j^2 \) is not meaningless either. Every term is \( j^2 \) and by the same rules, that sum is \( \frac{n(n+1)(2n+1)}{6} \). However the \( i \) was probably intended to be \( j \). Then the sum is \( 1 + 4 + 9 + 16 = 30 \).

**Question** What happens to these sums when the upper limits are changed to \( n \)?

**Answer** The sum depends on the stopping point \( n \). A formula is required (when possible). Integrals stop at \( x \), sums stop at \( n \), and we now look for special cases when \( f(x) \) or \( f_n \) can be found.

**A SPECIAL SUMMATION FORMULA**

How do you add the first 100 whole numbers? The problem is to compute

\[
\sum_{j=1}^{100} j = 1 + 2 + 3 + \cdots + 98 + 99 + 100 = ?
\]

\(^{\dagger}Zeno the Greek believed it was impossible to get anywhere, since he would only go halfway and then half again and half again. Infinite series would have changed his whole life.\)
If you were Gauss, you would see the answer at once. (He solved this problem at a ridiculous age, which gave his friends the idea of getting him into another class.) His solution was to combine 1 + 100, and 2 + 99, and 3 + 98, always adding to 101. There are fifty of those combinations. Thus the sum is \(50(101) = 5050\).

The sum from 1 to \(n\) uses the same idea. The first and last terms add to \(n + 1\). The next terms \(n - 1\) and 2 also add to \(n + 1\). If \(n\) is even (as 100 was) then there are \(\frac{1}{2}n\) parts. Therefore the sum is \(\frac{1}{2}n(n + 1)\):

\[
\sum_{j=1}^{n} j = 1 + 2 + \cdots + (n - 1) + n = \frac{1}{2}n(n + 1).
\]

The important term is \(\frac{1}{2}n^2\), but the exact sum is \(\frac{1}{2}n^2 + \frac{1}{2}n\).

What happens if \(n\) is an odd number (like \(n = 99\))? Formula (2) remains true. The combinations 1 + 99 and 2 + 98 still add to \(n + 1 = 100\). There are \(\frac{1}{2}(99) = 49\frac{1}{2}\) such pairs, because the middle term (which is 50) has nothing to combine with. Thus 1 + 2 + \cdots + 99 equals 49\frac{1}{2} times 100, or 4950.

Remark That sum had to be 4950, because it is 5050 minus 100. The sum up to 99 equals the sum up to 100 with the last term removed. Our key formula \(f_n - f_{n-1} = v_n\) has turned up again!

EXAMPLE Find the sum 101 + 102 + \cdots + 200 of the second hundred numbers.

First solution This is the sum from 1 to 200 minus the sum from 1 to 100:

\[
\sum_{j=1}^{200} j = \sum_{j=1}^{100} j + \sum_{j=101}^{200} j.
\]

The middle sum is \(\frac{1}{2}(200)(201)\) and the last is \(\frac{1}{2}(100)(101)\). Their difference is 15050. Note! I left out "\(j = \)" in the limits. It is there, but not written.

Second solution The answer 15050 is exactly the sum of the first hundred numbers (which was 5050) plus an additional 10000. Believing that a number like 10000 can never turn up by accident, we look for a reason. It is found through changing the limits of summation:

\[
\sum_{j=101}^{200} j = \sum_{k=1}^{100} (k + 100).
\]

This is important, to be able to shift limits around. Often the lower limit is moved to zero or one, for convenience. Both sums have 100 terms (that doesn’t change). The dummy variable \(j\) is replaced by another dummy variable \(k\). They are related by \(j = k + 100\) or equivalently by \(k = j - 100\).

The variable must change everywhere—in the lower limit and the upper limit as well as inside the sum. If \(j\) starts at 101, then \(k = j - 100\) starts at 1. If \(j\) ends at 200, \(k\) ends at 100. If \(j\) appears in the sum, it is replaced by \(k + 100\) (and if \(j^2\) appeared it would become \((k + 100)^2\)).

From equation (4) you see why the answer is 15050. The sum 1 + 2 + \cdots + 100 is 5050 as before. 100 is added to each of those 100 terms. That gives 10000.

EXAMPLES OF CHANGING THE VARIABLE (and the limits)

\[
\sum_{i=0}^{3} 2^i \text{ equals } \sum_{j=1}^{4} 2^{j-1} \text{ (here } i = j - 1)\]. Both sums are 1 + 2 + 4 + 8

\[
\sum_{i=3}^{n} v_i \text{ equals } \sum_{j=0}^{n-3} v_{j+3} \text{ (here } i = j + 3 \text{ and } j = i - 3\). Both sums are } v_3 + \cdots + v_n.
Why change $n$ to $n - 3$? Because the upper limit is $i = n$. So $j + 3 = n$ and $j = n - 3$.

A final step is possible, and you will often see it. The new variable $j$ can be changed back to $i$. Dummy variables have no meaning of their own, but at first the result looks surprising:

$$
\sum_{i=0}^{5} 2^i \text{ equals } \sum_{j=1}^{6} 2^{j-1} \text{ equals } \sum_{k=1}^{6} 2^{k-1}.
$$

With practice you might do that in one step, skipping the temporary letter $j$. Every $i$ on the left becomes $i - 1$ on the right. Then $i = 0, \ldots, 5$ changes to $i = 1, \ldots, 6$. (At first two steps are safer.) This may seem a minor point, but soon we will be changing the limits on integrals instead of sums. Integration is parallel to summation, and it is better to see a “change of variable” here first.

**Note about** $1 + 2 + \cdots + n$. The good thing is that Gauss found the sum $\frac{1}{2} n(n + 1)$. The bad thing is that his method looked too much like a trick. I would like to show how this fits the fundamental rule connecting sums and differences:

$$
\text{if } v_1 + v_2 + \cdots + v_n = f_n \text{ then } v_n = f_n - f_{n-1}.
$$

(5)

Gauss says that $f_n$ is $\frac{1}{2} n(n + 1)$. Reducing $n$ by 1, his formula for $f_{n-1}$ is $\frac{1}{2} (n - 1)n$. The difference $f_n - f_{n-1}$ should be the last term $n$ in the sum:

$$
f_n - f_{n-1} = \frac{1}{2} n(n + 1) - \frac{1}{2} (n - 1)n = \frac{1}{2} (n^2 + n - n^2 + n) = n.
$$

(6)

This is the one term $v_n = n$ that is included in $f_n$ but not in $f_{n-1}$.

There is a deeper point here. For any sum $f_n$, there are two things to check. The $f$'s must begin correctly and they must change correctly. The underlying idea is mathematical induction: Assume the statement is true below $n$. Prove it for $n$.

**Goal:** To prove that $1 + 2 + \cdots + n = \frac{1}{2} n(n + 1)$. This is the guess $f_n$.

**Proof by induction:** Check $f_1$ (it equals 1). Check $f_n - f_{n-1}$ (it equals $n$).

For $n = 1$ the answer $\frac{1}{2} n(n + 1) = \frac{1}{2} \cdot 1 \cdot 2$ is correct. For $n = 2$ this formula $\frac{1}{2} \cdot 2 \cdot 3$ agrees with $1 + 2$. But that separate test is not necessary! If $f_1$ is right, and if the change $f_n - f_{n-1}$ is right for every $n$, then $f_n$ must be right. Equation (6) was the key test, to show that the change in $f$'s agrees with $v$.

That is the logic behind mathematical induction, but I am not happy with most of the exercises that use it. There is absolutely no excitement. The answer is given by some higher power (like Gauss), and it is proved correct by some lower power (like us). It is much better when we lower powers find the answer for ourselves.† Therefore I will try to do that for the second problem, which is the **sum of squares**.

**THE SUM OF $j^2$ AND THE INTEGRAL OF $x^2$**

An important calculation comes next. It is the area in Figure 5.6. One region is made up of rectangles, so its area is a sum of $n$ pieces. The other region lies under the parabola $v = x^2$. It cannot be divided into rectangles, and calculus is needed.

The first problem is to find $f_n = 1^2 + 2^2 + 3^2 + \cdots + n^2$. This is a sum of squares, with $f_1 = 1$ and $f_2 = 5$ and $f_3 = 14$. The goal is to find the pattern in that sequence. By trying to guess $f_n$ we are copying what will soon be done for integrals.

Calculus looks for an $f(x)$ whose derivative is $v(x)$. There $f$ is an antiderivative (or

†The goal of real teaching is for the student to find the answer. And also the problem.
5.3 Summation versus Integration

Fig. 5.6 Rectangles enclosing \( v = x^2 \) have area \((\frac{1}{2}n^3 + \frac{1}{2}n^2 + \frac{1}{6}n)(\Delta x)^3 \approx \frac{1}{3}(n\Delta x)^3 = \frac{1}{3}x^3\).

an integral). Algebra looks for \( f_n \)'s whose differences produce \( v_n \). Here \( f_n \) could be called an antidifference (better to call it a sum).

The best start is a good guess. Copying directly from integrals, we might try \( f_n = \frac{1}{3}n^3 \). To test if it is right, check whether \( f_n - f_{n-1} \) produces \( v_n = n^2 \):

\[
\frac{1}{3}n^3 - \frac{1}{3}(n-1)^3 = \frac{1}{3}n^3 - \frac{1}{3}(n^3 - 3n^2 + 3n - 1) = n^2 - \frac{n}{3}.
\]

We see \( n^2 \), but also \( -n - \frac{1}{3} \). The guess \( \frac{1}{3}n^3 \) needs correction terms. To cancel \( \frac{1}{3} \) in the difference, I subtract \( \frac{1}{3}n \) from the sum. To put back \( n \) in the difference, I add \( 1 + 2 + \cdots + n = \frac{1}{2}n(n+1) \) to the sum. The new guess (which should be right) is

\[
f_n = \frac{1}{3}n^3 + \frac{1}{3}n(n+1) - \frac{1}{3}n = \frac{1}{3}n^3 + \frac{1}{2}n^2 + \frac{1}{6}n.
\]

(7)

To check this answer, verify first that \( f_1 = 1 \). Also \( f_2 = 5 \) and \( f_3 = 14 \). To be certain, verify that \( f_n - f_{n-1} = n^2 \). For calculus the important term is \( \frac{1}{3}n^3 \):

\[
\text{The sum } \sum_{j=1}^{n} j^2 \text{ of the first } n \text{ squares is } \frac{1}{3}n^3 \text{ plus corrections } \frac{1}{2}n^2 \text{ and } \frac{1}{6}n.
\]

In practice \( \frac{1}{3}n^3 \) is an excellent estimate. The sum of the first 100 squares is approximately \( \frac{1}{3}(100)^3 \), or a third of a million. If we need the exact answer, equation (7) is available: the sum is 338,350. Many applications (example: the number of steps to solve 100 linear equations) can settle for \( \frac{1}{3}n^3 \).

What is fascinating is the contrast with calculus. Calculus has no correction terms! They get washed away in the limit of thin rectangles. When the sum is replaced by the integral (the area), we get an absolutely clean answer:

The integral of \( v = x^2 \) from \( x = 0 \) to \( x = n \) is exactly \( \frac{1}{3}n^3 \).

The area under the parabola, out to the point \( x = 100 \), is precisely a third of a million. We have to explain why, with many rectangles.

The idea is to approach an infinite number of infinitely thin rectangles. A hundred rectangles gave an area of 338,350. Now take a thousand rectangles. Their heights are \((\frac{1}{10})^2, (\frac{1}{10})^2, \ldots\) because the curve is \( v = x^2 \). The base of every rectangle is \( \Delta x = \frac{1}{100} \), and we add heights times base:

\[
\text{area of rectangles } = \left( \frac{1}{10} \right)^2 \left( \frac{1}{10} \right) + \left( \frac{2}{10} \right)^2 \left( \frac{1}{10} \right) + \cdots + \left( \frac{1000}{10} \right)^2 \left( \frac{1}{10} \right).
\]

Factor out \( (\frac{1}{10})^3 \). What you have left is \( 1^2 + 2^2 + \cdots + 1000^2 \), which fits the sum of squares formula. The exact area of the thousand rectangles is 333,833.5. I could try to guess ten thousand rectangles but I won't.

Main point: The area is approaching 333,333.333.... But the calculations are getting worse. It is time for algebra—which means that we keep "\( \Delta x \)" and avoid numbers.
5 Integrals

The interval of length 100 is divided into \( n \) pieces of length \( \Delta x \). (Thus \( n = 100/\Delta x \).) The \( j \)th rectangle meets the curve \( v = x^2 \), so its height is \((j\Delta x)^2\). Its base is \( \Delta x \), and we add areas:

\[
\text{area} = (\Delta x)^2(\Delta x) + (2\Delta x)^2(\Delta x) + \cdots + (n\Delta x)^2(\Delta x) = \sum_{j=1}^{n} (j\Delta x)^2(\Delta x). \quad (8)
\]

Factor out \((\Delta x)^3\), leaving a sum of \( n \) squares. The area is \((\Delta x)^3\) times \( f_a \), and \( n = \frac{100}{\Delta x} \).

\[
(\Delta x)^3 \left[ \frac{1}{3} \left( \frac{100}{\Delta x} \right)^3 + \frac{1}{2} \left( \frac{100}{\Delta x} \right)^2 + \frac{1}{6} \left( \frac{100}{\Delta x} \right) \right] = \frac{1}{3} \cdot 100^3 + \frac{1}{2} \cdot 100^2(\Delta x) + \frac{1}{6} \cdot 100(\Delta x)^2. \quad (9)
\]

This equation shows what is happening. The leading term is a third of a million, as predicted. The other terms are approaching zero! They contain \( \Delta x \), and as the rectangles get thinner they disappear. They only account for the small corners of rectangles that lie above the curve. The vanishing of those corners will eventually be proved for any continuous functions—the area from the correction terms goes to zero—but here in equation (9) you see it explicitly.

The area under the curve came from the central idea of integration: \( 100/\Delta x \) rectangles of width \( \Delta x \) approach the limiting area \( \frac{1}{3}(100)^3 \). The rectangular area is \( \sum v_j \Delta x \). The exact area is \( \int v(x) \, dx \). In the limit \( \sum \) becomes \( \int \) and \( v_j \) becomes \( v(x) \) and \( \Delta x \) becomes \( dx \).

That completes the calculation for a parabola. It used the formula for a sum of squares, which was special. But the underlying idea is much more general. The limit of the sums agrees with the antiderivative: The antiderivative of \( v(x) = x^2 \) is \( f(x) = \frac{1}{3}x^3 \). According to the Fundamental Theorem, the area under \( v(x) \) is \( f(x) \):

\[
\int_{0}^{100} v(x) \, dx = f(100) - f(0) = \frac{1}{3}(100)^3.
\]

That Fundamental Theorem is not yet proved! I mean it is not proved by us. Whether Leibniz or Newton managed to prove it, I am not quite sure. But it can be done. Starting from sums of differences, the difficulty is that we have too many limits at once. The sums of \( r_j \Delta x \) are approaching the integral. The differences \( \Delta f/\Delta x \) approach the derivative. A real proof has to separate those steps, and Section 5.7 will do it.

Proved or not, you are seeing the main point. What was true for the numbers \( f_j \) and \( r_j \) is true in the limit for \( v(x) \) and \( f(x) \). Now \( v(x) \) can vary continuously, but it is still the slope of \( f(x) \). The reverse of slope is area.

\[
(1 + 2 + 3 + 4)^2 = 1^3 + 2^3 + 3^3 + 4^3
\]

Proof without words by Roger Nelsen (Mathematics Magazine 1990).

Finally we review the area under \( v = x \). The sum of \( 1 + 2 + \cdots + n \) is \( \frac{1}{2}n^2 + \frac{1}{2}n \). This gives the area of \( n = 4/\Delta x \) rectangles, going out to \( x = 4 \). The heights are \( j\Delta x \), the bases are \( \Delta x \), and we add areas:

\[
\sum_{j=1}^{4/\Delta x} (j\Delta x)(\Delta x) = (\Delta x)^2 \left[ \frac{1}{2} \left( \frac{4}{\Delta x} \right)^2 + \frac{1}{2} \left( \frac{4}{\Delta x} \right) \right] = 8 + 2\Delta x. \quad (10)
\]
5.3 Summation versus Integration

With $\Delta x = 1$ the area is $1 + 2 + 3 + 4 = 10$. With eight rectangles and $\Delta x = \frac{1}{8}$, the area was $8 + 2\Delta x = 9.625$. Sixteen rectangles of width $\frac{1}{16}$ brought the correction $2\Delta x$ down to $\frac{1}{2}$. The exact area is $8$. The error is proportional to $\Delta x$.

**Important note** There you see a question in applied mathematics. If there is an error, what size is it? How does it behave as $\Delta x \to 0$? The $\Delta x$ term disappears in the limit, and $(\Delta x)^2$ disappears faster. But to get an error of $10^{-6}$ we need **eight million rectangles**:

$$2\Delta x = 2 \cdot \frac{4}{8,000,000} = 10^{-6}.$$

That is horrifying! The numbers $10, 9, 8\frac{1}{2}, 8\frac{3}{4}, \ldots$ seem to approach the area $8$ in a satisfactory way, but the convergence is **much too slow**. It takes twice as much work to get one more binary digit in the answer—which is absolutely unacceptable. Somehow the $\Delta x$ term must be removed. If the correction is $(\Delta x)^2$ instead of $\Delta x$, then a thousand rectangles will reach an accuracy of $10^{-6}$.

The problem is that the rectangles are unbalanced. Their right sides touch the graph of $v$, but their left sides are much too high. The best is to cross the graph in the middle of the interval—this is the **midpoint rule**. Then the rectangle sits halfway across the line $v = x$, and the error is zero. Section 5.8 comes back to this rule—and to Simpson’s rule that fits parabolas and removes the $(\Delta x)^2$ term and is built into many calculators.

Finally we try the quick way. The area under $v = x$ is $\int x \, dx = \frac{1}{2}x^2$, because $df/dx = v$. The area out to $x = 4$ is $\frac{1}{2}(4)^2 = 8$. Done.

![Fig. 5.7 Endpoint rules: error $\sim 1/\text{work} \sim 1/n$. Midpoint rule is better: error $\sim 1/(\text{work})^2$.](image)

**Optional: $p$th powers** Our sums are following a pattern. First, $1 + \cdots + n$ is $\frac{1}{2}n^2$ plus $\frac{1}{2}n$. The sum of squares is $\frac{1}{3}n^3$ plus correction terms. The sum of $p$th powers is

$$1^p + 2^p + \cdots + n^p = \frac{1}{p+1} n^{p+1} + \text{correction terms.} \quad (11)$$

The correction involves lower powers of $n$, and you know what is coming. Those corrections disappear in calculus. The area under $v = x^p$ from 0 to $n$ is

$$\int_{x=0}^{n} x^p \, dx = \lim_{\Delta x \to 0} \sum_{j=1}^{n} (j\Delta x)^p (\Delta x) = \frac{1}{p+1} n^{p+\frac{1}{2}}. \quad (12)$$

Calculus doesn’t care if the upper limit $n$ is an integer, and it doesn’t care if the power $p$ is an integer. We only need $p + 1 > 0$ to be sure $n^{p+\frac{1}{2}}$ is genuinely the leading term. The antiderivative of $v = x^p$ is $f = x^{p+1}/(p + 1)$.

We are close to interesting experiments. The correction terms disappear and the sum approaches the integral. Here are actual numbers for $p = 1$, when the sum and integral are easy: $S_n = 1 + \cdots + n$ and $I_n = \int x \, dx = \frac{1}{2}n^2$. The difference is $D_n = \frac{1}{2}n$. The thing to watch is the relative error $E_n = D_n/I_n$:

<table>
<thead>
<tr>
<th>$n$</th>
<th>$S_n$</th>
<th>$I_n$</th>
<th>$D_n = S_n - I_n$</th>
<th>$E_n = D_n/I_n$</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>5050</td>
<td>5000</td>
<td>50</td>
<td>.010</td>
</tr>
<tr>
<td>200</td>
<td>20100</td>
<td>20000</td>
<td>100</td>
<td>.005</td>
</tr>
</tbody>
</table>
The number 20100 is \( f(200)(201) \). Please write down the next line \( n = 400 \), and please find a formula for \( E_n \). You can guess \( E_n \) from the table, or you can derive it from knowing \( S_n \) and \( I_n \). The formula should show that \( E_n \) goes to zero. More important, it should show how quick (or slow) that convergence will be.

One more number—a third of a million—was mentioned earlier. It came from integrating \( x^2 \) from 0 to 100, which compares to the sum \( S_{100} \) of 100 squares:

\[
\begin{array}{cccccc}
 n & p & S_n & I_n = \frac{1}{2}n^3 & D = S - I & E = D/I \\
 100 & 2 & 338350 & 333333\frac{1}{2} & 50164\frac{1}{2} & 0.01505 \\
 200 & 2 & 2686700 & 2666666\frac{1}{2} & 20033\frac{1}{2} & 0.0075125 \\
\end{array}
\]

These numbers suggest a new idea, to keep \( n \) fixed and change \( p \). The computer can find sums without a formula! With its help we go to fourth powers and square roots:

\[
\begin{array}{cccc}
 n & p & S = 1^p + \cdots + n^p & I = n^{p+1}/(p+1) \\
 100 & 4 & 2050333330 & 50333330 \\
 100 & \frac{1}{2} & 671.4629 & 4.7963 \\
\end{array}
\]

In this and future tables we don't expect exact values. The last entries are rounded off, and the goal is to see the pattern. The errors \( E_{n,p} \) are sure to obey a systematic rule—they are proportional to \( 1/n \) and to an unknown number \( C(p) \) that depends on \( p \). I hope you can push the experiments far enough to discover \( C(p) \). This is not an exercise with an answer in the back of the book—it is mathematics.

### 5.3 Exercises

**Read-through questions**

The Greek letter \( \sum \) indicates summation. In \( \sum v_j \) the dummy variable is \( b \). The limits are \( c \), so the first term is \( d \) and the last term is \( e \). When \( v_j = j \) this sum equals \( f \). For \( n = 100 \) the leading term is \( g \). The correction term is \( h \). The leading term equals the integral of \( x = x \) from 0 to 100, which is written \( i \). The sum is the total \( j \) of 100 rectangles. The correction term is the area between the \( k \) and the \( l \).

The sum \( \sum_{i=3}^{5} i^2 \) is the same as \( \sum_{i=1}^{4} m \) and equals \( n \). The sum \( \sum_{i=4}^{5} v_j \) is the same as \( \sum \alpha \). When \( v_{j+1} = \alpha \) and equals \( p \). For \( f_{n+1} = \sum_{i=1}^{n} v_j \) the difference \( f_{n+1} - f_n \) equals \( q \).

The formula for \( 1^2 + 2^2 + \cdots + n^2 \) is \( f_n = \sum r \). To prove it by mathematical induction, check \( f_1 = s \) and check \( f_n - f_{n-1} = t \). The area under the parabola \( v = x^2 \) from \( x = 0 \) to \( x = 9 \) is \( u \). This is close to the area of \( v \) rectangles of base \( \Delta x \). The correction terms approach zero very \( w \).

1. Compute the numbers \( \sum_{i=1}^{4} 1/i \) and \( \sum_{i=2}^{5} (2i - 3) \).
2. Compute \( \sum_{j=0}^{3} (j^2 - j) \) and \( \sum_{j=1}^{5} 1/2^j \).
3. Evaluate the sum \( \sum_{i=0}^{6} 2^i \) and \( \sum_{i=6}^{n} 2^i \).
4. Evaluate \( \sum_{j=1}^{n} (-1)^j \) and \( \sum_{j=1}^{n} (-1)^{j+1} \).
5. Write these sums in sigma notation and compute them:
   \[ 2^4 + 4 + 6 + \cdots + 100 \quad 1 + 3 + 5 + \cdots + 199 \quad 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} \]
6. Express these sums in sigma notation:
   \[ v_1 - v_2 + v_3 - v_4 + v_6 \]
7. Convert these sums to sigma notation:
   \[ a_0 + a_1 x + \cdots + a_n x^n \]
8. The binomial formula uses coefficients \( \binom{n}{j} = \frac{n!}{j!(n-j)!} \):
   \[ (a + b)^n = \binom{n}{0} a^n + \binom{n}{1} a^{n-1} b + \cdots + \binom{n}{n} b^n = \sum_{j=0}^{n} \binom{n}{j} b^j \]
9. With electronic help compute \( \sum_{i=1}^{100} 1/i \) and \( \sum_{i=1}^{100} 1/i \).
10. On a computer find \( \sum_{i=1}^{10} (-1)^{i+1} \) times \( \sum_{i=1}^{10} 1/i! \).
11 Simplify \( \sum_{i=1}^{n} (a_i + b_i)^2 + \sum_{i=1}^{n} (a_i - b_i)^2 \) to \( \sum_{i=1}^{n} \) \[ \text{unless} \]

12 Show that \( \left( \sum_{i=1}^{n} a_i \right)^2 \neq \sum_{i=1}^{n} a_i^2 \) and \( \sum_{i=1}^{n} a_ib_i \neq \sum_{i=1}^{n} a_i \sum_{i=1}^{n} b_i \).

13 "Telecope" the sums \( \sum_{i=1}^{n} (2^i - 2^{i-1}) \) and \( \sum_{i=1}^{n} \left( \frac{1}{i+1} - \frac{1}{i} \right) \).

All but two terms cancel.

14 Simplify the sums \( \sum_{j=1}^{n} (f_j - f_{j-1}) \) and \( \sum_{j=3}^{n} (f_{j+1} - f_j) \).

15 True or false: (a) \( \sum_{j=4}^{n} v_j = \sum_{j=2}^{n} v_{j-2} \) (b) \( \sum_{i=1}^{9} v_i = \sum_{i=3}^{11} v_{i-2} \)

16 \( \sum_{i=1}^{n} v_i = \sum_{j=0}^{n-1} \) and \( \sum_{j=0}^{n} j^2 = \sum_{i=2}^{n} \).

17 The antiderivative of \( d^2 f/dx^2 \) is \( df/dx \). What is the sum \( (f_2 - 2f_1 + f_0) + (f_3 - 2f_2 + f_1) + \ldots + (f_n - 2f_{n-1} + f_{n-2})? \)

18 Induction: Verify that \( 1^2 + 2^2 + \ldots + n^2 = \frac{n(n+1)(2n+1)}{6} \) by checking that \( f_1 \) is correct and \( f_n - f_{n-1} = n^2 \).

19 Prove by induction: \( 1 + 3 + \ldots + (2n-1) = n^2 \).

20 Verify that \( 1^3 + 2^3 + \ldots + n^3 = \frac{n^2(n+1)^2}{4} \) by checking \( f_1 \) and \( f_n - f_{n-1} \). The text has a proof without words.

21 Suppose \( f_n \) has the form \( an + bn^2 + cn^3 \). If you know \( f_1 = 1, f_2 = 5, f_3 = 14 \), turn those into three equations for \( a, b, c \) that give what formula?

22 Find \( q \) in the formula \( 1^p + \ldots + n^p = \sum_{i=1}^{p} \).

23 Add \( n = 400 \) to the table for \( S_n = 1 + \ldots + n \) and find the relative error \( E_n \). Guess and prove a formula for \( E_n \).

24 Add \( n = 50 \) to the table for \( S_{50} = 1^2 + \ldots + n^2 \) and compute \( E_{50} \). Find an approximate formula for \( E_{50} \).

25 Add \( p = \frac{1}{4} \) and \( p = 3 \) to the table for \( S_{100,p} = 1^p + \ldots + 100^p \). Guess an approximate formula for \( E_{100,p} \).

26 Guess \( C(p) \) in the formula \( E_{n,p} \approx C(p)/n \).

27 Show that \( |1 - 5| < |1| + |5| \). Always \( |v_1 + v_2| < |v_1| + |v_2| \) unless \( \text{unless} \)

28 Let \( S \) be the sum \( 1 + x + x^2 + \ldots \) of the (infinite) geometric series. Then \( xS = x + x^2 + x^3 + \ldots \) is the same as \( S \) minus \( \text{unless} \). Therefore \( S = \text{unless} \). None of this makes sense if \( x = 2 \) because \( \text{unless} \).

29 The double sum \( \sum_{i=1}^{3} \left[ \sum_{j=1}^{3} (i+j) \right] = v_1 + \sum_{i=1}^{3} (1 + i) \) plus \( v_2 = \sum_{j=1}^{3} (2 + j) \). Compute \( v_1 \) and \( v_2 \) and the double sum.

30 The double sum \( \sum_{i=1}^{3} \left( \sum_{j=1}^{3} w_{ij} \right) = (w_{1,1} + w_{1,2} + w_{1,3}) + \ldots \). The double sum \( \sum_{j=1}^{3} \left( \sum_{i=1}^{3} w_{ij} \right) \) is \( (w_{1,1} + w_{2,1}) + (w_{1,2} + w_{2,2}) + \ldots \). Compare.

31 Find the flaw in the proof that \( 2^n = 1 \) for every \( n = 0, 1, 2, \ldots \). For \( n = 0 \) we have \( 2^0 = 1 \). If \( 2^n = 1 \) for every \( n < N \), then \( 2^n = 2^{n-1} \cdot 2^n = 2^{n-2} = 1 \cdot 1/1 = 1 \).

32 Write out all terms to see why the following are true:

\[ \sum_{i=1}^{3} \sum_{j=1}^{3} u_{ij} v_{ij} = \sum_{i=1}^{3} u_{ij} \sum_{j=1}^{3} v_{ij} \]

33 The average of \( 6, 11, 4 \) is \( \bar{v} = \frac{1}{3}(6 + 11 + 4) \). Then the average of \( v_1, v_2, v_3 \) is \( \bar{v} = \frac{1}{3} \). Prove that \( \sum (v_i - \bar{v}) = 0 \).

34 The Schwarz inequality is \( \left( \sum_{i=1}^{n} a_i b_i \right)^2 \leq \left( \sum_{i=1}^{n} a_i^2 \right) \left( \sum_{i=1}^{n} b_i^2 \right) \).

Compute both sides if \( a_1 = 2, a_2 = 3, b_1 = 1, b_2 = 4 \). Then compute both sides for any \( a_1, a_2, b_1, b_2 \). The proof in Section 11.1 uses vectors.

35 Suppose \( n \) rectangles with base \( \Delta x \) touch the graph of \( u(x) \) at the points \( x = \Delta x, 2\Delta x, \ldots, n\Delta x \). Express the total rectangular area in sigma notation.

36 If \( \Delta x \) rectangles with base \( \Delta x \) touch the graph of \( u(x) \) at the left end of each interval (thus at \( x = 0, \Delta x, 2\Delta x, \ldots \)) express the total area in sigma notation.

37 The sum \( \Delta x \sum_{j=1}^{n} f(j\Delta x) = f(\sum_{j=1}^{n} (j-1)\Delta x) \) equals \( \text{unless} \). In the limit this becomes \( \int_{0}^{\infty} \text{unless} \) \( dx = \text{unless} \).
search for an antiderivative may not succeed. We may not find \( f \). In that case we go back to rectangles, or on to something better in Section 5.8.

A computer is ready to integrate \( v \), but not by discovering \( f \). It integrates between specified limits, to obtain a number (the definite integral). Here we hope to find a function (the indefinite integral). That requires a symbolic integration code like MACSYMA or Mathematica or MAPLE, or a reasonably nice \( v(x) \), or both. An expression for \( f(x) \) can have tremendous advantages over a list of numbers.

Thus our goal is to find antiderivatives and use them. The techniques will be further developed in Chapter 7—this section is short but good. First we write down what we know. On each line, \( f(x) \) is an antiderivative of \( v(x) \) because \( df/dx = v(x) \).

<table>

</table>

You recognize that each integration formula came directly from a differentiation formula. The integral of the cosine is the sine, because the derivative of the sine is the cosine. For emphasis we list three derivatives above three integrals:

\[
\frac{d}{dx} (\text{constant}) = 0 \quad \frac{d}{dx} (x) = 1 \quad \frac{d}{dx} \left( \frac{x^{n+1}}{n+1} \right) = x^n
\]

\[
\int 0 \, dx = C \quad \int 1 \, dx = x + C \quad \int x^n \, dx = \frac{x^{n+1}}{n+1} + C
\]

There are two ways to make this list longer. One is to find the derivative of a new \( f(x) \). Then \( f \) goes in one column and \( v = df/dx \) goes in the other column.† The other possibility is to use rules for derivatives to find rules for integrals. That is the way to extend the list, enormously and easily.

**RULES FOR INTEGRALS**

Among the rules for derivatives, three were of supreme importance. They were linearity, the product rule, and the chain rule. Everything flowed from those three. In the

†We will soon meet \( e^x \), which goes in both columns. It is \( f(x) \) and also \( v(x) \).
reverse direction (from \( v \) to \( f \)) this is still true. The three basic methods of differential calculus also dominate integral calculus:

\[
\text{linearity of derivatives} \rightarrow \text{linearity of integrals}
\]

\[
\text{product rule for derivatives} \rightarrow \text{integration by parts}
\]

\[
\text{chain rule for derivatives} \rightarrow \text{integrals by substitution}
\]

The easiest is linearity, which comes first. Integration by parts will be left for Section 7.1. This section starts on substitutions, reversing the chain rule to make an integral simpler.

**LINEARITY OF INTEGRALS**

What is the integral of \( v(x) + w(x) \)? Add the two separate integrals. The graph of \( v + w \) has two regions below it, the area under \( v \) and the area from \( v \) to \( v + w \). Adding areas gives the sum rule. Suppose \( f \) and \( g \) are antiderivatives of \( v \) and \( w \):

- **sum rule**: \( f + g \) is an antiderivative of \( v + w \)
- **constant rule**: \( cf \) is an antiderivative of \( cv \)
- **linearity**: \( af + bg \) is an antiderivative of \( av + bw \)

This is a case of overkill. The first two rules are special cases of the third, so logically the last rule is enough. However it is so important to deal quickly with constants—just “factor them out”—that the rule \( cv \rightarrow cf \) is stated separately. The proofs come from the linearity of derivatives: \( (af + bg)' \text{ equals } af' + bg' \text{ which equals } av + bw \). The rules can be restated with integral signs:

- **sum rule**: \( \int [v(x) + w(x)] \, dx = \int v(x) \, dx + \int w(x) \, dx \)
- **constant rule**: \( \int cv \, dx = c \int v \, dx \)
- **linearity**: \( \int [av(x) - bw(x)] \, dx = a \int v(x) \, dx + b \int w(x) \, dx \)

*Note about the constant in \( f(x) + C \). All antiderivatives allow the addition of a constant. For a combination like \( av(x) + bw(x) \), the antiderivative is \( af(x) + bg(x) + C \). The constants for each part combine into a single constant. To give all possible antiderivatives of a function, just remember to write “\( + C \)” after one of them. The real problem is to find that one antiderivative.*

**EXAMPLE 1** The antiderivative of \( v = x^2 + x^{-2} \) is \( f = x^3/3 + (x^{-1})/(-1) + C \).

**EXAMPLE 2** The antiderivative of \( 6 \cos t + 7 \sin t \) is \( 6 \sin t - 7 \cos t + C \).

**EXAMPLE 3** Rewrite \( \frac{1}{1 - \sin x} \) as \( \frac{1 - \sin x}{1 - \sin^2 x} = \frac{1 - \sin x}{\cos^2 x} = \sec^2 x - \sec x \tan x \).

The antiderivative is \( \tan x - \sec x + C \). That rewriting is done by a symbolic algebra code (or by you). Differentiation is often simple, so most people check that \( df \cdot dx = v(x) \).

**Question** How to integrate \( \tan^2 x \)?

**Method** Write it as \( \sec^2 x - 1 \). **Answer** \( \tan x - x + C \).
We now present the most valuable technique in this section—substitution. To see the idea, you have to remember the chain rule:

- \( f(g(x)) \) has derivative \( f'(g(x))(dg/dx) \)
- \( \sin x^2 \) has derivative \( \cos x^2)(2x) \)
- \( (x^3 + 1)^5 \) has derivative \( 5(x^3 + 1)^4(3x^2) \)

If the function on the right is given, the function on the left is its antiderivative! There are two points to emphasize right away:

1. **Constants are no problem—they can always be fixed.** Divide by 2 or 15:

   \[
   \int x \cos(x^2) \, dx = \frac{1}{2} \sin(x^2) + C \quad \int x^2(x^3 + 1)^4 \, dx = \frac{1}{15} (x^3 + 1)^5 + C
   \]

   Notice the 2 from \( x^2 \), the 5 from the fifth power, and the 3 from \( x^3 \).

2. **Choosing the inside function \( g \) (or \( u \)) commits us to its derivative:**

   - the integral of \( 2x \cos x^2 \) is \( \sin x^2 + C \) \( (g = x^2, \, dg/dx = 2x) \)
   - the integral of \( \cos x^2 \) is (failure) \( (no \, dg/dx) \)
   - the integral of \( x^2 \cos x^2 \) is (failure) \( (wrong \, dg/dx) \)

   To substitute \( g \) for \( x^2 \), we need its derivative. The trick is to spot an inside function whose derivative is present. We can fix constants like 2 or 15, but otherwise \( dg/dx \) has to be there. *Very often the inside function \( g \) is written \( u \).* We use that letter to state the substitution rule, when \( f \) is the integral of \( v \):

\[
\int v(u(x)) \frac{du}{dx} \, dx = f(u(x)) + C. \tag{1}
\]

**EXAMPLE 4** \( \int \sin x \cos x \, dx = \frac{1}{2}(\sin x)^2 + C \quad u = \sin x \) (compare Example 6)

**EXAMPLE 5** \( \int \sin^2 x \cos x \, dx = \frac{1}{2}(\sin x)^3 + C \quad u = \sin x \)

**EXAMPLE 6** \( \int \cos x \sin x \, dx = -\frac{1}{2}(\cos x)^2 + C \quad u = \cos x \) (compare Example 4)

**EXAMPLE 7** \( \int \tan^4 x \sec^2 x \, dx = \frac{1}{2}(\tan x)^5 + C \quad u = \tan x \)

The next example has \( u = x^2 - 1 \) and \( du/dx = 2x \). The key step is choosing \( u \):

**EXAMPLE 8** \( \int x \, dx/\sqrt{x^2 - 1} = \sqrt{x^2 - 1} + C \quad \int x \sqrt{x^2 - 1} \, dx = \frac{1}{2}(x^2 - 1)^{3/2} + C \)

A *shift* of \( x \) (to \( x + 2 \)) or a *multiple* of \( x \) (rescaling to \( 2x \)) is particularly easy:

**EXAMPLES 9–10** \( \int (x + 2)^3 \, dx = \frac{1}{4}(x + 2)^4 + C \quad \int \cos 2x \, dx = \frac{1}{2} \sin 2x + C \)

You will soon be able to do those in your sleep. Officially the derivative of \( (x + 2)^4 \) uses the chain rule. But the inside function \( u = x + 2 \) has \( du/dx = 1 \). The "1" is there automatically, and the graph shifts over—as in Figure 5.8b.

For Example 10 the inside function is \( u = 2x \). Its derivative is \( du/dx = 2 \). This
5.4 Indefinite Integrals and Substitutions

Fig. 5.8 Substituting $u = x + 1$ and $u = 2x$ and $u = x^2$. The last graph has half of $du/dx = 2x$.

required factor 2 is missing in $\int \cos 2x \, dx$, but we put it there by multiplying and dividing by 2. Check the derivative of $\frac{1}{3} \sin 2x$: the 2 from the chain rule cancels the $\frac{1}{3}$. The rule for any nonzero constant is similar:

$$\int v(x + c) \, dx = f(x + c) \quad \text{and} \quad \int v(cx) \, dx = \frac{1}{c} f(cx). \quad (2)$$

Squeezing the graph by $c$ divides the area by $c$. Now $3x + 7$ rescales and shifts:

**EXAMPLE 11**

$$\int \cos (3x + 7) \, dx = \frac{1}{3} \sin (3x + 7) + C \quad \int (3x + 7)^2 \, dx = \frac{1}{3} \cdot \frac{1}{2} (3x + 7)^3 + C$$

**Remark on writing down the steps** When the substitution is complicated, it is a good idea to get $du/dx$ where you need it. Here $3x^2 + 1$ needs $6x$:

$$\int 7x(3x^2 + 1)^4 \, dx = \frac{7}{6} \int (3x^2 + 1)^4 6x \, dx = \frac{7}{6} \int u^4 \frac{du}{dx} \, dx$$

Now integrate:

$$\frac{7 u^5}{6} + C = \frac{7}{6} \frac{u^5}{5} + C. \quad (3)$$

Check the derivative at the end. The exponent 5 cancels 5 in the denominator, $6x$ from the chain rule cancels 6, and $7x$ is what we started with.

**Remark on differentials** In place of $(du/dx) \, dx$, many people just write $du$:

$$\int (3x^2 + 1)^4 6x \, dx = \int u^4 \, du = \frac{1}{5} u^5 + C. \quad (4)$$

This really shows how substitution works. We switch from $x$ to $u$, and we also switch from $dx$ to $du$. The most common mistake is to confuse $dx$ with $du$. The factor $du/dx$ from the chain rule is absolutely needed, to reach $du$. The change of variables (dummy variables anyway!) leaves an easy integral, and then $u$ turns back into $3x^2 + 1$. Here are the four steps to substitute $u$ for $x$:

1. Choose $u(x)$ and compute $du/dx$  
2. Locate $v(u)$ times $du/dx$ times $dx$, or $v(u)$ times $du$  
3. Integrate $\int v(u) \, du$ to find $f(u) + C$  
4. Substitute $u(x)$ back into this antiderivative $f$.

**EXAMPLE 12**

$$\int \sqrt{\cos x} \, dx = \frac{2}{2} \sqrt{x} = \int \cos u \, du = \sin u + C = \sin \sqrt{x} + C$$

*(put in $u$) (integrate) (put back $x$)*

The choice of $u$ must be right, to change everything from $x$ to $u$. With ingenuity, some remarkable integrals are possible. But most will remain impossible forever. The functions $\cos x^2$ and $1/\sqrt{4 - \sin^2 x}$ have no "elementary" antiderivative. Those integrals are well defined and they come up in applications—the latter gives the distance
Integrals around an ellipse. That can be computed to tremendous accuracy, but not to perfect accuracy.

The exercises concentrate on substitutions, which need and deserve practice. We give a nonexample—\( \int (x^2 + 1)^2 \, dx \) does not equal \( \frac{1}{3} (x^2 + 1)^3 \)—to emphasize the need for \( du/dx \). Since \( 2x \) is missing, \( u = x^2 + 1 \) does not work. But we can fix up \( \pi \):

\[
\int \sin \pi x \, dx = \int \sin u \frac{du}{\pi} = -\frac{1}{\pi} \cos u + C = -\frac{1}{\pi} \cos \pi x + C.
\]

### 5.4 Exercises

#### Read-through Questions

Finding integrals by substitution is the reverse of the \( \frac{d}{dx} \) rule. The derivative of \( \sin x \) is \( \cos x \). Therefore the antiderivative of \( \cos x \) is \( \sin x \). To compute \( \int (1 + \sin x) \cos x \, dx \), substitute \( u = \sin x \). Then \( du/dx = 1 \) so substitute \( du = 1 \). In terms of \( u \) the integral is \( \int \frac{u}{1} \, du = \frac{u}{2} + C \). Returning to \( x \) gives the final answer.

The best substitutions for \( \int \tan (x + 3) \sec^2 (x + 3) \, dx \) and \( \int (x^2 + 1)^{10} x \, dx \) are \( u = x^2 + 1 \) and \( u = x^2 + 1 \). Then \( du = 2x \, dx \) and \( m \). The antiderivative of \( v \, du/dx \) is \( \int 2x \, dx/(1 + x^2) \) leads to \( \int \frac{a}{u} \, du \), which we don't yet know. The integral \( \int dx/(1 + x^2) \) is known immediately as \( \tan^{-1} x \).

#### Find the indefinite integrals in 1–20.

1. \( \int \sqrt{2 + x} \, dx \) (add + C)
2. \( \int \sqrt{3 - x} \, dx \) (always + C)
3. \( \int (x + 1)^3 \, dx \)
4. \( \int (x + 1)^{-3} \, dx \)
5. \( \int (x^2 + 1)^5 \, dx \)
6. \( \int \sqrt{1 - 3x} \, dx \)
7. \( \int \cos^3 x \sin x \, dx \)
8. \( \int \cos x \, dx / \sin^3 x \)
9. \( \int \cos^2 2x \, dx \)
10. \( \int \cos x \, dx / \sin 2x \, dx \)
11. \( \int dt / \sqrt{1 - t^2} \)
12. \( \int t \sqrt{1 - t^2} \, dt \)
13. \( \int t^3 \, dt / \sqrt{1 + t^2} \)
14. \( \int (1 + \sqrt{x}) \, dx / \sqrt{x} \)
15. \( \int \sec x \, dx \)
16. \( \int \sec x \tan x \, dx \)
17. \( \int \sec^2 x \tan^2 x \, dx \)
18. \( \int \sin^3 x \, dx \)

In 21–32 find a function \( y(x) \) that solves the differential equation.

21. \( dy/dx = x^2 + \sqrt{x} \)
22. \( dy/dx = y^2 \) (try \( y = cx^2 \))
23. \( dy/dx = \sqrt{1 - 2x} \)
24. \( dy/dx = 1 / \sqrt{1 - 2x} \)

25. \( dy/dx = 1/y \)
26. \( dy/dx = x/y \)
27. \( d^2 y/dx^2 = 1 \)
28. \( d^5 y/dx^5 = 1 \)
29. \( d^2 y/dx^2 = -y \)
30. \( dy/dx = \sqrt{xy} \)
31. \( d^2 y/dx^2 = \sqrt{x} \)
32. \( (dy/dx)^2 = \sqrt{x} \)

33. True or false, when \( f \) is an antiderivative of \( v \):

(a) \( \int v(u(x)) \, dx = f(u(x)) + C \)
(b) \( \int v^2(x) \, dx = \frac{1}{2} f^2(x) + C \)
(c) \( \int v(x) \, dx = f(u(x)) + C \)
(d) \( \int v(x) \, dx = \frac{1}{2} f^2(x) + C \)

34. True or false, when \( f \) is an antiderivative of \( v \):

(a) \( \int f(x) \, dv(x) \, dx = \frac{1}{2} f^2(x) + C \)
(b) \( \int v(x) \, du(x) \, dx = f(v(x)) + C \)
(c) \( \int (x^2 + 1)^2 \, dx \) is not \( \frac{1}{3} (x^2 + 1)^3 \) but \( \frac{1}{3} (x^2 + 1)^3 \)
(d) \( \int (x^2 + 1)^3 \, dx \) is \( \int u \, du \) which will soon be \( \ln u \).

Show that \( \int 2x \, dx / (1 + x^2) \) is \( \int (u - 1) \, du / u^3 \).

The acceleration \( d^2 f / dt^2 = 9.8 \) gives \( f(t) = \) (two integration constants).

The solution to \( d^4 f / dx^4 = 0 \) is (four constants).

42. If \( f(t) \) is an antiderivative of \( v(t) \), find antiderivatives of

(a) \( v(t + 3) \)
(b) \( v(t + 3) \)
(c) \( 3v(t) \)
(d) \( v(3t) \).
